The **`ForkingMixIn`** class is used in the same way, except that the server will spawn a new process for each request. Available only on POSIX platforms that support **`fork()`**.

`http.server` — HTTP servers

Source code: Lib/http/server.py [https://github.com/python/cpython/tree/3.11/Lib/http/server.py]

This module defines classes for implementing HTTP servers.

Warning

`http.server` is not recommended for production. It only implements basic security checks.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

One class, `HTTPServer`, is a `socketserver.TCPServer` subclass. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```
def run(server_class=HTTPServer, handler_class=BaseHTTPR
    server_address = ('', 8000)
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

class http.server.HTTPServer(*server_address*, *RequestHandlerClass*)

This class builds on the `TCPServer` class by storing the server address as instance variables named **`server_name`** and **`server_port`**. The server is accessible by the handler, typically through the handler's **`server`** instance variable.

class http.server.ThreadingHTTPServer(*server_address*, *RequestHandlerClass*)

This class is identical to HTTPServer but uses threads to handle requests by using the **ThreadingMixIn**. This is useful to handle web browsers pre-opening sockets, on which **HTTPServer** would wait indefinitely.

New in version 3.7.

The **HTTPServer** and **ThreadingHTTPServer** must be given a *RequestHandlerClass* on instantiation, of which this module provides three different variants:

class http.server.BaseHTTPRequestHandler(*request*, *client_address*, *server*)

This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). **BaseHTTPRequestHandler** provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method `SPAM`, the **do_SPAM()** method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the **__init__()** method.

BaseHTTPRequestHandler has the following instance variables:

client_address

Contains a tuple of the form `(host, port)` referring to the client's address.

server

Contains the server instance.

close_connection

Boolean that should be set before **`handle_one_request()`** returns, indicating if another request may be expected, or if the connection should be shut down.

requestline

Contains the string representation of the HTTP request line. The terminating CRLF is stripped. This attribute should be set by **`handle_one_request()`**. If no valid request line was processed, it should be set to the empty string.

command

Contains the command (request type). For example, `'GET'`.

path

Contains the request path. If query component of the URL is present, then `path` includes the query. Using the terminology of **RFC 3986** [https://datatracker.ietf.org/doc/html/rfc3986.html], `path` here includes `hier-part` and the `query`.

request_version

Contains the version string from the request. For example, `'HTTP/1.0'`.

headers

Holds an instance of the class specified by the **`MessageClass`** class variable. This instance parses and manages the headers in the HTTP request. The **`parse_headers()`** function from **`http.client`** is used to parse the headers and it requires that the HTTP request provide a valid **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html] style header.

rfile

An **io.BufferedIOBase** input stream, ready to read from the start of the optional input data.

wfile

Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream in order to achieve successful interoperation with HTTP clients.

Changed in version 3.6: This is an **io.BufferedIOBase** stream.

BaseHTTPRequestHandler has the following attributes:

server_version

Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, `'BaseHTTP/0.2'`.

sys_version

Contains the Python system version, in a form usable by the **version_string** method and the **server_version** class variable. For example, `'Python/1.4'`.

error_message_format

Specifies a format string that should be used by **send_error()** method for building an error response to the client. The string is filled by default with variables from **responses** based on the status code that passed to **send_error()**.

error_content_type

Specifies the Content-Type HTTP header of error responses sent to the client. The default value is `'text/html'`.

protocol_version

Specifies the HTTP version to which the server is conformant. It is sent in responses to let the client know the server's communication capabilities for future requests. If set to `'HTTP/1.1'`, the server will permit HTTP persistent connections; however, your server *must* then include an accurate `Content-Length` header (using **`send_header()`**) in all of its responses to clients. For backwards compatibility, the setting defaults to `'HTTP/1.0'`.

MessageClass

Specifies an **`email.message.Message`**-like class to parse HTTP headers. Typically, this is not overridden, and it defaults to **`http.client.HTTPMessage`**.

responses

This attribute contains a mapping of error code integers to two-element tuples containing a short and long message. For example, `{code: (shortmessage, longmessage)}`. The *shortmessage* is usually used as the *message* key in an error response, and *longmessage* as the *explain* key. It is used by **`send_response_only()`** and **`send_error()`** methods.

A **`BaseHTTPRequestHandler`** instance has the following methods:

handle()

Calls **`handle_one_request()`** once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate **`do_*()`** methods.

handle_one_request()

This method will parse and dispatch the request to the

appropriate **`do_*()`** method. You should never need to override it.

handle_expect_100()

When an HTTP/1.1 conformant server receives an `Expect: 100-continue` request header it responds back with a `100 Continue` followed by `200 OK` headers. This method can be overridden to raise an error if the server does not want the client to continue. For e.g. server can choose to send `417 Expectation Failed` as a response header and `return False`.

New in version 3.2.

send_error(*code*, *message*=*None*, *explain*=*None*)

Sends and logs a complete error reply to the client. The numeric *code* specifies the HTTP error code, with *message* as an optional, short, human readable description of the error. The *explain* argument can be used to provide more detailed information about the error; it will be formatted using the **`error_message_format`** attribute and emitted, after a complete set of headers, as the response body. The **`responses`** attribute holds the default values for *message* and *explain* that will be used if no value is provided; for unknown codes the default value for both is the string `???`. The body will be empty if the method is HEAD or the response code is one of the following: `1xx`, `204 No Content`, `205 Reset Content`, `304 Not Modified`.

Changed in version 3.4: The error response includes a Content-Length header. Added the *explain* argument.

send_response(*code*, *message*=*None*)

Adds a response header to the headers buffer and logs the accepted request. The HTTP response line is written to the internal buffer, followed by *Server* and *Date* headers. The values for these two headers are picked up

from the **version_string()** and **date_time_string()** methods, respectively. If the server does not intend to send any other headers using the **send_header()** method, then **send_response()** should be followed by an **end_headers()** call.

Changed in version 3.3: Headers are stored to an internal buffer and **end_headers()** needs to be called explicitly.

send_header(*keyword*, *value*)

Adds the HTTP header to an internal buffer which will be written to the output stream when either **end_headers()** or **flush_headers()** is invoked. *keyword* should specify the header keyword, with *value* specifying its value. Note that, after the send_header calls are done, **end_headers()** MUST BE called in order to complete the operation.

Changed in version 3.2: Headers are stored in an internal buffer.

send_response_only(*code*, *message*=*None*)

Sends the response header only, used for the purposes when `100 Continue` response is sent by the server to the client. The headers not buffered and sent directly the output stream.If the *message* is not specified, the HTTP message corresponding the response *code* is sent.

New in version 3.2.

end_headers()

Adds a blank line (indicating the end of the HTTP headers in the response) to the headers buffer and calls **flush_headers()**.

Changed in version 3.2: The buffered headers are written to the output stream.

flush_headers()

Finally send the headers to the output stream and flush the internal headers buffer.

New in version 3.3.

log_request(*code*='-', *size*='-')

Logs an accepted (successful) request. *code* should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the *size* parameter.

log_error(...)

Logs an error when a request cannot be fulfilled. By default, it passes the message to **`log_message()`**, so it takes the same arguments (*format* and additional values).

log_message(*format*, ...)

Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The *format* argument is a standard printf-style format string, where the additional arguments to **`log_message()`** are applied as inputs to the formatting. The client ip address and current date and time are prefixed to every message logged.

version_string()

Returns the server software's version string. This is a combination of the **`server_version`** and **`sys_version`** attributes.

date_time_string(*timestamp*=*None*)

Returns the date and time given by *timestamp* (which must be `None` or in the format returned by **`time.time()`**), formatted for a message header. If *timestamp* is omitted, it uses the current date and time.

The result looks like `'Sun, 06 Nov 1994 08:49:37 GMT'`.

log_date_time_string()

Returns the current date and time, formatted for logging.

address_string()

Returns the client address.

Changed in version 3.3: Previously, a name lookup was performed. To avoid name resolution delays, it now always returns the IP address.

class http.server.SimpleHTTPRequestHandler(*request*, *client_address*, *server*, *directory=None*)

This class serves files from the directory *directory* and below, or the current directory if *directory* is not provided, directly mapping the directory structure to HTTP requests.

New in version 3.7: The *directory* parameter.

Changed in version 3.9: The *directory* parameter accepts a path-like object.

A lot of the work, such as parsing the request, is done by the base class **`BaseHTTPRequestHandler`**. This class implements the **`do_GET()`** and **`do_HEAD()`** functions.

The following are defined as class-level attributes of **`SimpleHTTPRequestHandler`**:

server_version

This will be `"SimpleHTTP/" + __version__`, where `__version__` is defined at the module level.

extensions_map

A dictionary mapping suffixes into MIME types,

contains custom overrides for the default system mappings. The mapping is used case-insensitively, and so should contain only lower-cased keys.

Changed in version 3.9: This dictionary is no longer filled with the default system mappings, but only contains overrides.

The **SimpleHTTPRequestHandler** class defines the following methods:

do_HEAD()

This method serves the `'HEAD'` request type: it sends the headers it would send for the equivalent `GET` request. See the **do_GET()** method for a more complete explanation of the possible headers.

do_GET()

The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named `index.html` or `index.htm` (in that order). If found, the file's contents are returned; otherwise a directory listing is generated by calling the **list_directory()** method. This method uses **os.listdir()** to scan the directory, and returns a `404` error response if the **listdir()** fails.

If the request was mapped to a file, it is opened. Any **OSError** exception in opening the requested file is mapped to a `404`, `'File not found'` error. If there was a `'If-Modified-Since'` header in the request, and the file was not modified after this time, a `304`, `'Not Modified'` response is sent. Otherwise, the content type is guessed by calling the **guess_type()** method, which in turn uses the *extensions_map* variable,

and the file contents are returned.

A `'Content-type:'` header with the guessed content type is output, followed by a `'Content-Length:'` header with the file's size and a `'Last-Modified:'` header with the file's modification time.

Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file's MIME type starts with `text/` the file is opened in text mode; otherwise binary mode is used.

For example usage, see the implementation of the `test` function in Lib/http/server.py [https://github.com/python/cpython/tree/3.11/Lib/http/server.py].

Changed in version 3.7: Support of the `'If-Modified-Since'` header.

The **`SimpleHTTPRequestHandler`** class can be used in the following manner in order to create a very basic webserver serving files relative to the current directory:

```
import http.server
import socketserver

PORT = 8000

Handler = http.server.SimpleHTTPRequestHandler

with socketserver.TCPServer(("", PORT), Handler) as http
    print("serving at port", PORT)
    httpd.serve_forever()
```

`http.server` can also be invoked directly using the **`-m`** switch of the interpreter. Similar to the previous example, this serves files relative to the current directory:

```
python -m http.server
```

The server listens to port 8000 by default. The default can be

overridden by passing the desired port number as an argument:

```
python -m http.server 9000
```

By default, the server binds itself to all interfaces. The option `-b/--bind` specifies a specific address to which it should bind. Both IPv4 and IPv6 addresses are supported. For example, the following command causes the server to bind to localhost only:

```
python -m http.server --bind 127.0.0.1
```

New in version 3.4: `--bind` argument was introduced.

New in version 3.8: `--bind` argument enhanced to support IPv6

By default, the server uses the current directory. The option `-d/--directory` specifies a directory to which it should serve the files. For example, the following command uses a specific directory:

```
python -m http.server --directory /tmp/
```

New in version 3.7: `--directory` argument was introduced.

By default, the server is conformant to HTTP/1.0. The option `-p/--protocol` specifies the HTTP version to which the server is conformant. For example, the following command runs an HTTP/1.1 conformant server:

```
python -m http.server --protocol HTTP/1.1
```

New in version 3.11: `--protocol` argument was introduced.

class http.server.CGIHTTPRequestHandler(*request*, *client_address*, *server*)

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in **`SimpleHTTPRequestHandler`**.

Note

CGI scripts run by the **CGIHTTPRequestHandler** class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat special extensions as denoting CGI scripts.

The **do_GET()** and **do_HEAD()** functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the `cgi_directories` path.

The **CGIHTTPRequestHandler** defines the following data member:

cgi_directories

This defaults to `['/cgi-bin', '/htbin']` and describes directories to treat as containing CGI scripts.

The **CGIHTTPRequestHandler** defines the following method:

do_POST()

This method serves the `'POST'` request type, only allowed for CGI scripts. Error 501, “Can only POST to CGI scripts”, is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

CGIHTTPRequestHandler can be enabled in the command line by passing the `--cgi` option:

```
python -m http.server --cgi
```

Security Considerations

SimpleHTTPRequestHandler will follow symbolic links when handling requests, this makes it possible for files outside of the specified directory to be served.

Earlier versions of Python did not scrub control characters from the log messages emitted to stderr from `python -m http.server` or the default **BaseHTTPRequestHandler** `.log_message` implementation. This could allow remote clients connecting to your server to send nefarious control codes to your terminal.

New in version 3.11.1: Control characters are scrubbed in stderr logs.

`http.cookies` — HTTP state management

Source code: Lib/http/cookies.py [https://github.com/python/cpython/tree/3.11/Lib/http/cookies.py]

The `http.cookies` module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] and **RFC 2068** [https://datatracker.ietf.org/doc/html/rfc2068.html] specifications. It has since been discovered that MSIE 3.0x doesn't follow the character rules outlined in those specs and also many current day browsers and servers have relaxed parsing rules when comes to Cookie handling. As a result, the parsing rules used are a bit less strict.

The character set, `string.ascii_letters`, `string.digits` and `!#$%&'*+-.^_`|~:` denote the set of valid characters allowed by this module in Cookie name (as `key`).

Changed in version 3.3: Allowed ':' as a valid Cookie name character.

Note

On encountering an invalid cookie, `CookieError` is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch `CookieError` on parsing.

exception http.cookies.CookieError

Exception failing because of **RFC 2109** [https://

datatracker.ietf.org/doc/html/rfc2109.html] invalidity: incorrect attributes, incorrect *Set-Cookie* header, etc.

class http.cookies.BaseCookie([*input*])

This class is a dictionary-like object whose keys are strings and whose values are **Morsel** instances. Note that upon setting a key to a value, the value is first converted to a **Morsel** containing the key and the value.

If *input* is given, it is passed to the **load()** method.

class http.cookies.SimpleCookie([*input*])

This class derives from **BaseCookie** and overrides **value_decode()** and **value_encode()**. SimpleCookie supports strings as cookie values. When setting the value, SimpleCookie calls the builtin **str()** to convert the value to a string. Values received from HTTP are kept as strings.

See also

Module http.cookiejar
HTTP cookie handling for web *clients*. The **http.cookiejar** and **http.cookies** modules do not depend on each other.

RFC 2109 [https://datatracker.ietf.org/doc/html/rfc2109.html] - HTTP State Management Mechanism
This is the state management specification implemented by this module.

Cookie Objects

BaseCookie.value_decode(*val*)

Return a tuple `(real_value, coded_value)` from a string representation. `real_value` can be any type. This method does no decoding in **BaseCookie** — it exists so it can be overridden.

BaseCookie.value_encode(*val*)

Return a tuple `(real_value, coded_value)`. *val* can be any type, but `coded_value` will always be converted to a string. This method does no encoding in **`BaseCookie`** — it exists so it can be overridden.

In general, it should be the case that **`value_encode()`** and **`value_decode()`** are inverses on the range of *value_decode*.

BaseCookie.output(*attrs=None*, *header='Set-Cookie:'*, *sep='\r\n'*)

Return a string representation suitable to be sent as HTTP headers. *attrs* and *header* are sent to each **`Morsel`**'s **`output()`** method. *sep* is used to join the headers together, and is by default the combination `'\r\n'` (CRLF).

BaseCookie.js_output(*attrs=None*)

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for *attrs* is the same as in **`output()`**.

BaseCookie.load(*rawdata*)

If *rawdata* is a string, parse it as an `HTTP_COOKIE` and add the values found there as **`Morsel`**s. If it is a dictionary, it is equivalent to:

```
for k, v in rawdata.items():
    cookie[k] = v
```

Morsel Objects

class http.cookies.Morsel

Abstract a key/value pair, which has some **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] attributes.

Morsels are dictionary-like objects, whose set of keys is constant — the valid **RFC 2109** [https://datatracker.ietf.org/doc/

html/rfc2109.html] attributes, which are

- `expires`
- `path`
- `comment`
- `domain`
- `max-age`
- `secure`
- `version`
- `httponly`
- `samesite`

The attribute **`httponly`** specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

The attribute **`samesite`** specifies that the browser is not allowed to send the cookie along with cross-site requests. This helps to mitigate CSRF attacks. Valid values for this attribute are “Strict” and “Lax”.

The keys are case-insensitive and their default value is `''`.

Changed in version 3.5: **`__eq__()`** now takes **`key`** and **`value`** into account.

Changed in version 3.7: Attributes **`key`**, **`value`** and **`coded_value`** are read-only. Use **`set()`** for setting them.

Changed in version 3.8: Added support for the **`samesite`** attribute.

Morsel.value

The value of the cookie.

Morsel.coded_value

The encoded value of the cookie — this is what should be sent.

Morsel.key

The name of the cookie.

Morsel.set(*key*, *value*, *coded_value*)

Set the *key*, *value* and *coded_value* attributes.

Morsel.isReservedKey(*K*)

Whether *K* is a member of the set of keys of a **`Morsel`**.

Morsel.output(*attrs*=*None*, *header*=*'Set-Cookie:'*)

Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless *attrs* is given, in which case it should be a list of attributes to use. *header* is by default `"Set-Cookie:"`.

Morsel.js_output(*attrs*=*None*)

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

The meaning for *attrs* is the same as in **`output()`**.

Morsel.OutputString(*attrs*=*None*)

Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

The meaning for *attrs* is the same as in **`output()`**.

Morsel.update(*values*)

Update the values in the Morsel dictionary with the values in the dictionary *values*. Raise an error if any of the keys in the *values* dict is not a valid **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] attribute.

Changed in version 3.5: an error is raised for invalid keys.

Morsel.copy(*value*)

Return a shallow copy of the Morsel object.

Changed in version 3.5: return a Morsel object instead of a dict.

Morsel.setdefault(*key*, *value*=*None*)

Raise an error if key is not a valid **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] attribute, otherwise behave the same as `dict.setdefault()`.

Example

The following example demonstrates how to use the `http.cookies` module.

```
>>> from http import cookies
>>> C = cookies.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print(C) # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print(C.output()) # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = cookies.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]["path"] = "/cookie"
>>> print(C.output(header="Cookie:"))
Cookie: rocky=road; Path=/cookie
>>> print(C.output(attrs=[], header="Cookie:"))
Cookie: rocky=road
>>> C = cookies.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger") # load from a st
>>> print(C)
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = cookies.SimpleCookie()
```

```
>>> C.load('keebler="E=everybody; L=\\"Loves\\"; fudge=\
>>> print(C)
Set-Cookie: keebler="E=everybody; L=\"Loves\"; fudge=\01
>>> C = cookies.SimpleCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]["path"] = "/"
>>> print(C)
Set-Cookie: oreo=doublestuff; Path=/
>>> C = cookies.SimpleCookie()
>>> C["twix"] = "none for you"
>>> C["twix"].value
'none for you'
>>> C = cookies.SimpleCookie()
>>> C["number"] = 7 # equivalent to C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"].value
'7'
>>> C["string"].value
'seven'
>>> print(C)
Set-Cookie: number=7
Set-Cookie: string=seven
```

`http.cookiejar` — Cookie handling for HTTP clients

Source code: Lib/http/cookiejar.py [https://github.com/python/cpython/tree/3.11/Lib/http/cookiejar.py]

The `http.cookiejar` module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – *cookies* – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] are handled. RFC 2965 handling is switched off by default. **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the 'policy' in effect. Note that the great majority of cookies on the internet are Netscape cookies. `http.cookiejar` attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the `max-age` and `port` cookie-attributes introduced with RFC 2965.

Note

The various named parameters found in *Set-Cookie* and *Set-Cookie2* headers (eg. `domain` and `expires`) are conventionally referred to as *attributes*. To distinguish them from Python attributes, the documentation for this module uses the term *cookie-attribute* instead.

The module defines the following exception:

exception http.cookiejar.LoadError

Instances of **FileCookieJar** raise this exception on failure to load cookies from a file. **LoadError** is a subclass of **OSError**.

Changed in version 3.3: LoadError was made a subclass of **OSError** instead of **IOError**.

The following classes are provided:

class http.cookiejar.CookieJar(*policy=None*)

policy is an object implementing the **CookiePolicy** interface.

The **CookieJar** class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. **CookieJar** instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.

class http.cookiejar.FileCookieJar(*filename=None*, *delayload=None*, *policy=None*)

policy is an object implementing the **CookiePolicy** interface. For the other arguments, see the documentation for the corresponding attributes.

A **CookieJar** which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are **NOT** loaded from the named file until either the **load()** or **revert()** method is called. Subclasses of this class are documented in section FileCookieJar subclasses and co-operation with web browsers.

This should not be initialized directly – use its subclasses below instead.

Changed in version 3.8: The filename parameter supports a path-like object.

class http.cookiejar.CookiePolicy

This class is responsible for deciding whether each cookie should be accepted from / returned to the server.

class http.cookiejar.DefaultCookiePolicy(*blocked_domains=None*, *allowed_domains=None*, *netscape=True*, *rfc2965=False*, *rfc2109_as_netscape=None*, *hide_cookie2=False*, *strict_domain=False*, *strict_rfc2965_unverifiable=True*, *strict_ns_unverifiable=False*, *strict_ns_domain=DefaultCookiePolicy.DomainLiberal*, *strict_ns_set_initial_dollar=False*, *strict_ns_set_path=False*, *secure_protocols=('https', 'wss')*)

Constructor arguments should be passed as keyword arguments only. *blocked_domains* is a sequence of domain names that we never accept cookies from, nor return cookies to. *allowed_domains* if not **None**, this is a sequence of the only domains for which we accept and return cookies. *secure_protocols* is a sequence of protocols for which secure cookies can be added to. By default *https* and *wss* (secure websocket) are considered secure protocols. For all other arguments, see the documentation for **CookiePolicy** and **DefaultCookiePolicy** objects.

DefaultCookiePolicy implements the standard accept / reject rules for Netscape and **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] cookies. By default, **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] cookies (ie. cookies received in a *Set-Cookie* header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or **rfc2109_as_netscape** is `True`, RFC 2109 cookies are 'downgraded' by the **CookieJar** instance to Netscape cookies, by setting the **version** attribute of the **Cookie** instance to 0. **DefaultCookiePolicy** also provides some parameters to allow some fine-tuning of policy.

class http.cookiejar.Cookie

This class represents Netscape, **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] and **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] cookies. It is not expected

that users of **http.cookiejar** construct their own **Cookie** instances. Instead, if necessary, call **make_cookies()** on a **CookieJar** instance.

See also

Module **urllib.request**
URL opening with automatic cookie handling.

Module **http.cookies**
HTTP cookie classes, principally useful for server-side code. The **http.cookiejar** and **http.cookies** modules do not depend on each other.

https://curl.se/rfc/cookie_spec.html
The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the 'Netscape cookie protocol' implemented by all the major browsers (and **http.cookiejar**) only bears a passing resemblance to the one sketched out in `cookie_spec.html`.

RFC 2109 [https://datatracker.ietf.org/doc/html/rfc2109.html] - HTTP State Management Mechanism
Obsoleted by **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html]. Uses *Set-Cookie* with version = 1.

RFC 2965 [https://datatracker.ietf.org/doc/html/rfc2965.html] - HTTP State Management Mechanism
The Netscape protocol with the bugs fixed. Uses *Set-Cookie2* in place of *Set-Cookie*. Not widely used.

http://kristol.org/cookie/errata.html
Unfinished errata to **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html].

RFC 2964 [https://datatracker.ietf.org/doc/html/rfc2964.html] - Use of HTTP State Management

CookieJar and FileCookieJar Objects

CookieJar objects support the iterator protocol for iterating over contained **Cookie** objects.

CookieJar has the following methods:

CookieJar.add_cookie_header(*request*)

Add correct *Cookie* header to *request*.

If policy allows (ie. the **rfc2965** and **hide_cookie2** attributes of the **CookieJar**'s **CookiePolicy** instance are true and false respectively), the *Cookie2* header is also added when appropriate.

The *request* object (usually a **urllib.request.Request** instance) must support the methods **get_full_url()**, **has_header()**, **get_header()**, **header_items()**, **add_unredirected_header()** and the attributes **host**, **type**, **unverifiable** and **origin_req_host** as documented by **urllib.request**.

Changed in version 3.3: request object needs **origin_req_host** attribute. Dependency on a deprecated method **get_origin_req_host()** has been removed.

CookieJar.extract_cookies(*response*, *request*)

Extract cookies from HTTP *response* and store them in the **CookieJar**, where allowed by policy.

The **CookieJar** will look for allowable *Set-Cookie* and *Set-Cookie2* headers in the *response* argument, and store cookies as appropriate (subject to the **CookiePolicy.set_ok()** method's approval).

The *response* object (usually the result of a call to **urllib.request.urlopen()**, or similar) should support an **info()** method, which returns an **email.message.Message** instance.

The *request* object (usually a **urllib.request.Request** instance) must support the method **get_full_url()** and the attributes **host**, **unverifiable** and **origin_req_host**, as documented by **urllib.request**. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

Changed in version 3.3: *request* object needs **origin_req_host** attribute. Dependency on a deprecated method **get_origin_req_host()** has been removed.

CookieJar.set_policy(*policy*)

Set the **CookiePolicy** instance to be used.

CookieJar.make_cookies(*response*, *request*)

Return sequence of **Cookie** objects extracted from *response* object.

See the documentation for **extract_cookies()** for the interfaces required of the *response* and *request* arguments.

CookieJar.set_cookie_if_ok(*cookie*, *request*)

Set a **Cookie** if policy says it's OK to do so.

CookieJar.set_cookie(*cookie*)

Set a **Cookie**, without checking with policy to see whether or not it should be set.

CookieJar.clear([*domain*[, *path*[, *name*]]])

Clear some cookies.

If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that *domain* will be removed. If given two arguments, cookies belonging to the specified *domain* and URL *path* are removed. If given three arguments, then the cookie with the specified *domain*, *path* and *name* is removed.

Raises **KeyError** if no matching cookie exists.

CookieJar.clear_session_cookies()

Discard all session cookies.

Discards all contained cookies that have a true **discard** attribute (usually because they had either no `max-age` or `expires` cookie-attribute, or an explicit `discard` cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.

Note that the **save()** method won't save session cookies anyway, unless you ask otherwise by passing a true *ignore_discard* argument.

FileCookieJar implements the following additional methods:

FileCookieJar.save(*filename*=*None*, *ignore_discard*=*False*, *ignore_expires*=*False*)

Save cookies to a file.

This base class raises **NotImplementedError**. Subclasses may leave this method unimplemented.

filename is the name of file in which to save cookies. If *filename* is not specified, **self.filename** is used (whose default is the value passed to the constructor, if any); if **self.filename** is **None**, **ValueError** is raised.

ignore_discard: save even cookies set to be discarded.
ignore_expires: save even cookies that have expired

The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the **load()** or **revert()** methods.

FileCookieJar.load(*filename*=*None*, *ignore_discard*=*False*, *ignore_expires*=*False*)

Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for `save()`.

The named file must be in the format understood by the class, or `LoadError` will be raised. Also, `OSError` may be raised, for example if the file does not exist.

Changed in version 3.3: `IOError` used to be raised, it is now an alias of `OSError`.

FileCookieJar.revert(*filename*=*None*, *ignore_discard*=*False*, *ignore_expires*=*False*)

Clear all cookies and reload cookies from a saved file.

`revert()` can raise the same exceptions as `load()`. If there is a failure, the object's state will not be altered.

`FileCookieJar` instances have the following public attributes:

FileCookieJar.filename

Filename of default file in which to keep cookies. This attribute may be assigned to.

FileCookieJar.delayload

If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects performance, not behaviour (unless the cookies on disk are changing). A `CookieJar` object may ignore it. None of the `FileCookieJar` classes included in the standard library lazily loads cookies.

FileCookieJar subclasses and co-operation with web browsers

The following `CookieJar` subclasses are provided for reading and writing.

class http.cookiejar.MozillaCookieJar(*filename=None*, *delayload=None*, *policy=None*)

A **FileCookieJar** that can load from and save cookies to disk in the Mozilla `cookies.txt` file format (which is also used by curl and the Lynx and Netscape browsers).

Note

This loses information about **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] cookies, and also about newer or non-standard cookie-attributes such as `port`.

Warning

Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

class http.cookiejar.LWPCookieJar(*filename=None*, *delayload=None*, *policy=None*)

A **FileCookieJar** that can load from and save cookies to disk in format compatible with the libwww-perl library's `Set-Cookie3` file format. This is convenient if you want to store cookies in a human-readable file.

Changed in version 3.8: The filename parameter supports a path-like object.

CookiePolicy Objects

Objects implementing the **CookiePolicy** interface have the following methods:

CookiePolicy.set_ok(*cookie*, *request*)

Return boolean value indicating whether cookie should be accepted from server.

cookie is a **`Cookie`** instance. *request* is an object implementing the interface defined by the documentation for **`CookieJar.extract_cookies()`**.

CookiePolicy.return_ok(*cookie*, *request*)

Return boolean value indicating whether cookie should be returned to server.

cookie is a **`Cookie`** instance. *request* is an object implementing the interface defined by the documentation for **`CookieJar.add_cookie_header()`**.

CookiePolicy.domain_return_ok(*domain*, *request*)

Return `False` if cookies should not be returned, given cookie domain.

This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from **`domain_return_ok()`** and **`path_return_ok()`** leaves all the work to **`return_ok()`**.

If **`domain_return_ok()`** returns true for the cookie domain, **`path_return_ok()`** is called for the cookie path. Otherwise, **`path_return_ok()`** and **`return_ok()`** are never called for that cookie domain. If **`path_return_ok()`** returns true, **`return_ok()`** is called with the **`Cookie`** object itself for a full check. Otherwise, **`return_ok()`** is never called for that cookie path.

Note that **`domain_return_ok()`** is called for every *cookie* domain, not just for the *request* domain. For example, the function might be called with both `".example.com"` and `"www.example.com"` if the request domain is `"www.example.com"`. The same goes for

path_return_ok().

The *request* argument is as documented for **return_ok()**.

CookiePolicy.path_return_ok(*path*, *request*)

Return `False` if cookies should not be returned, given cookie path.

See the documentation for **domain_return_ok()**.

In addition to implementing the methods above, implementations of the **CookiePolicy** interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

CookiePolicy.netscape

Implement Netscape protocol.

CookiePolicy.rfc2965

Implement **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] protocol.

CookiePolicy.hide_cookie2

Don't add *Cookie2* header to requests (the presence of this header indicates to the server that we understand **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] cookies).

The most useful way to define a **CookiePolicy** class is by subclassing from **DefaultCookiePolicy** and overriding some or all of the methods above. **CookiePolicy** itself may be used as a 'null policy' to allow setting and receiving any and all cookies (this is unlikely to be useful).

DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] and

Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks:

```
import http.cookiejar
class MyCookiePolicy(http.cookiejar.DefaultCookiePolicy)
    def set_ok(self, cookie, request):
        if not http.cookiejar.DefaultCookiePolicy.set_ok
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the **`CookiePolicy`** interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blocklist and allowlist is provided (both off by default). Only domains not in the blocklist and present in the allowlist (if the allowlist is active) participate in cookie setting and returning. Use the *blocked_domains* constructor argument, and **`blocked_domains()`** and **`set_blocked_domains()`** methods (and the corresponding argument and methods for *allowed_domains*). If you set an allowlist, you can turn it off again by setting it to **`None`**.

Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, `"example.com"` matches a blocklist entry of `"example.com"`, but `"www.example.com"` does not. Domains that do start with a dot are matched by more specific domains too. For example, both `"www.example.com"` and `"www.coyote.example.com"` match `".example.com"` (but `"example.com"` itself does not). IP addresses are an exception, and must match exactly. For example, if

blocked_domains contains `"192.168.1.2"` and `".168.1.2"`, 192.168.1.2 is blocked, but 193.168.1.2 is not.

DefaultCookiePolicy implements the following additional methods:

DefaultCookiePolicy.blocked_domains()

Return the sequence of blocked domains (as a tuple).

DefaultCookiePolicy.set_blocked_domains(*blocked_domains*)

Set the sequence of blocked domains.

DefaultCookiePolicy.is_blocked(*domain*)

Return `True` if *domain* is on the blocklist for setting or receiving cookies.

DefaultCookiePolicy.allowed_domains()

Return **None**, or the sequence of allowed domains (as a tuple).

DefaultCookiePolicy.set_allowed_domains(*allowed_domains*)

Set the sequence of allowed domains, or **None**.

DefaultCookiePolicy.is_not_allowed(*domain*)

Return `True` if *domain* is not on the allowlist for setting or receiving cookies.

DefaultCookiePolicy instances have the following attributes, which are all initialised from the constructor arguments of the same name, and which may all be assigned to.

DefaultCookiePolicy.rfc2109_as_netscape

If true, request that the **CookieJar** instance downgrade **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] cookies (ie. cookies received in a *Set-Cookie* header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the **Cookie** instance to 0. The default

value is `None`, in which case RFC 2109 cookies are downgraded if and only if **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

General strictness switches:

DefaultCookiePolicy.strict_domain

Don't allow sites to set two-component domains with country-code top-level domains like `.co.uk`, `.gov.uk`, `.co.nz`.etc. This is far from perfect and isn't guaranteed to work!

RFC 2965 [https://datatracker.ietf.org/doc/html/rfc2965.html] protocol strictness switches:

DefaultCookiePolicy.strict_rfc2965_unverifiable

Follow **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are *never* blocked on the basis of verifiability

Netscape protocol strictness switches:

DefaultCookiePolicy.strict_ns_unverifiable

Apply **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] rules on unverifiable transactions even to Netscape cookies.

DefaultCookiePolicy.strict_ns_domain

Flags indicating how strict to be with domain-matching rules for Netscape cookies. See below for acceptable values.

DefaultCookiePolicy.strict_ns_set_initial_dollar

Ignore cookies in Set-Cookie: headers that have names starting with `'$'`.

DefaultCookiePolicy.strict_ns_set_path

Don't allow setting cookies whose path doesn't path-match request URI.

`strict_ns_domain` is a collection of flags. Its value is constructed by or-ing together (for example, `DomainStrictNoDots|DomainStrictNonDomain` means both flags are set).

DefaultCookiePolicy.DomainStrictNoDots

When setting cookies, the 'host prefix' must not contain a dot (eg. `www.foo.bar.com` can't set a cookie for `.bar.com`, because `www.foo` contains a dot).

DefaultCookiePolicy.DomainStrictNonDomain

Cookies that did not explicitly specify a `domain` cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. `spam.example.com` won't be returned cookies from `example.com` that had no `domain` cookie-attribute).

DefaultCookiePolicy.DomainRFC2965Match

When setting cookies, require a full **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags:

DefaultCookiePolicy.DomainLiberal

Equivalent to 0 (ie. all of the above Netscape domain strictness flags switched off).

DefaultCookiePolicy.DomainStrict

Equivalent to `DomainStrictNoDots|DomainStrictNonDomain`.

Cookie Objects

`Cookie` instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie

standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the `max-age` and `expires` cookie-attributes contain equivalent information, and because **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] cookies may be 'downgraded' by **`http.cookiejar`** from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a **`CookiePolicy`** method. The class does not enforce internal consistency, so you should know what you're doing if you do that.

Cookie.version

> Integer or **`None`**. Netscape cookies have **`version`** 0. **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] and **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] cookies have a `version` cookie-attribute of 1. However, note that **`http.cookiejar`** may 'downgrade' RFC 2109 cookies to Netscape cookies, in which case **`version`** is 0.

Cookie.name

> Cookie name (a string).

Cookie.value

> Cookie value (a string), or **`None`**.

Cookie.port

> String representing a port or a set of ports (eg. '80', or '80,8080'), or **`None`**.

Cookie.path

> Cookie path (a string, eg. `'/acme/rocket_launchers'`).

Cookie.secure

> `True` if cookie should only be returned over a secure connection.

Cookie.expires

Integer expiry date in seconds since epoch, or **None**. See also the **is_expired()** method.

Cookie.discard

`True` if this is a session cookie.

Cookie.comment

String comment from the server explaining the function of this cookie, or **None**.

Cookie.comment_url

URL linking to a comment from the server explaining the function of this cookie, or **None**.

Cookie.rfc2109

`True` if this cookie was received as an **RFC 2109** [https://datatracker.ietf.org/doc/html/rfc2109.html] cookie (ie. the cookie arrived in a *Set-Cookie* header, and the value of the Version cookie-attribute in that header was 1). This attribute is provided because **http.cookiejar** may 'downgrade' RFC 2109 cookies to Netscape cookies, in which case **version** is 0.

Cookie.port_specified

`True` if a port or set of ports was explicitly specified by the server (in the *Set-Cookie* / *Set-Cookie2* header).

Cookie.domain_specified

`True` if a domain was explicitly specified by the server.

Cookie.domain_initial_dot

`True` if the domain explicitly specified by the server began with a dot (`'.'`).

Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods:

Cookie.has_nonstandard_attr(*name*)

Return `True` if cookie has the named cookie-attribute.

Cookie.get_nonstandard_attr(*name*, *default*=*None*)

If cookie has the named cookie-attribute, return its value. Otherwise, return *default*.

Cookie.set_nonstandard_attr(*name*, *value*)

Set the value of the named cookie-attribute.

The **`Cookie`** class also defines the following method:

Cookie.is_expired(*now*=*None*)

`True` if cookie has passed the time at which the server requested it should expire. If *now* is given (in seconds since the epoch), return whether the cookie has expired at the specified time.

Examples

The first example shows the most common usage of **`http.cookiejar`**:

```
import http.cookiejar, urllib.request
cj = http.cookiejar.CookieJar()
opener = urllib.request.build_opener(urllib.request.HTTP
r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file):

```
import os, http.cookiejar, urllib.request
cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".netscape
opener = urllib.request.build_opener(urllib.request.HTTP
r = opener.open("http://example.com/")
```

The next example illustrates the use of **DefaultCookiePolicy**. Turn on **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html] cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned:

```
import urllib.request
from http.cookiejar import CookieJar, DefaultCookiePolic
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=Policy.DomainStrict,
    blocked_domains=["ads.net", ".ads.net"])
cj = CookieJar(policy)
opener = urllib.request.build_opener(urllib.request.HTTP
r = opener.open("http://example.com/")
```

`xmlrpc` — XMLRPC server and client modules

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data.

`xmlrpc` is a package that collects server and client modules implementing XML-RPC. The modules are:

- **`xmlrpc.client`**
- **`xmlrpc.server`**

`xmlrpc.client` — XML-RPC client access

Source code: Lib/xmlrpc/client.py [https://github.com/python/cpython/tree/3.11/Lib/xmlrpc/client.py]

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP(S) as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

Warning

The `xmlrpc.client` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

Changed in version 3.5: For HTTPS URIs, `xmlrpc.client` now performs all the necessary certificate and hostname checks by default.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

class xmlrpc.client.ServerProxy(*uri*, *transport=None*, *encoding=None*, *verbose=False*, *allow_none=False*, *use_datetime=False*, *use_builtin_types=False*, ***, *headers=()*, *context=None*)

A **ServerProxy** instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal **SafeTransport** instance for https: URLs and an internal HTTP **Transport** instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag.

The following parameters govern the use of the returned proxy instance. If *allow_none* is true, the Python constant `None` will be translated into XML; the default behaviour is for `None` to raise a **TypeError**. This is a commonly used extension to the XML-RPC specification, but isn't supported by all clients and servers; see http://ontosys.com/xml-rpc/extensions.php [https://web.archive.org/web/20130120074804/http://ontosys.com/xml-rpc/extensions.php] for a description. The *use_builtin_types* flag can be used to cause date/time values to be presented as **datetime.datetime** objects and binary data to be presented as **bytes** objects; this flag is false by default. **datetime.datetime**, **bytes** and **bytearray** objects may be passed to calls. The *headers* parameter is an optional sequence of HTTP headers to send with each request, expressed as a sequence of 2-tuples representing the header name and value. (e.g. `[('Header-Name', 'value')]`). The obsolete *use_datetime* flag is similar to *use_builtin_types* but it applies only to date/time values.

Changed in version 3.3: The *use_builtin_types* flag was added.

Changed in version 3.8: The *headers* parameter was added.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: `http://user:pass@host:port/path`. The `user:pass` portion will be base64-encoded as an HTTP 'Authorization' header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password. If an HTTPS

URL is provided, *context* may be **ssl.SSLContext** and configures the SSL settings of the underlying HTTPS connection.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type):

XML-RPC type	Python type
boolean	**bool**. The values are `True` and `False`.
int, **i1**, **i2**, **i4**, **i8** or **biginteger**	**int** in range from -2147483648 to 2147483647. Values get the `<int>` tag.
double or **float**	**float**. Values get the `<double>` tag.
string	**str**
array	**list** or **tuple** containing conformable elements. Arrays are returned as **lists**.
struct	**dict**. Keys must be strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their **__dict__** attribute is transmitted.
dateTime.iso8601	**DateTime** or **datetime.datetime**. Returned type depends on values of *use_builtin_types* and *use_datetime* flags.
base64	**Binary**, **bytes** or **bytearray**. Returned type depends on the value of the *use_builtin_types* flag.
nil	The `None` constant. Passing is allowed only if *allow_none* is true.
bigdecimal	**decimal.Decimal**. Returned type only.

This is the full set of data types supported by XML-RPC. Method calls may also raise a special **Fault** instance, used to signal XML-RPC server errors, or **ProtocolError** used to signal an error in the HTTP/HTTPS transport layer. Both **Fault** and **ProtocolError** derive from a base class called **Error**. Note that the xmlrpc client module currently does not marshal instances of subclasses of built-in types.

When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it's the caller's

responsibility to ensure that the string is free of characters that aren't allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn't well-formed XML. If you have to pass arbitrary bytes via XML-RPC, use **`bytes`** or **`bytearray`** classes or the **`Binary`** wrapper class described below.

`Server` is retained as an alias for **`ServerProxy`** for backwards compatibility. New code should use **`ServerProxy`**.

Changed in version 3.5: Added the *context* argument.

Changed in version 3.6: Added support of type tags with prefixes (e.g. `ex:nil`). Added support of unmarshalling additional types used by Apache XML-RPC implementation for numerics: `i1`, `i2`, `i8`, `biginteger`, `float` and `bigdecimal`. See https://ws.apache.org/xmlrpc/types.html for a description.

: A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

XML-RPC Introspection [https://xmlrpc-c.sourceforge.net/introspection.html]
: Describes the XML-RPC protocol extension for introspection.

XML-RPC Specification [http://xmlrpc.scripting.com/spec.html]
: The official specification.

ServerProxy Objects

A **`ServerProxy`** instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument

signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a **`Fault`** or **`ProtocolError`** object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved **`system`** attribute:

ServerProxy.system.listMethods()

> This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

ServerProxy.system.methodSignature(*name*)

> This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.
>
> Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.
>
> Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply “string, array”. If it expects three integers and returns a string, its signature is “string, int, int, int”.
>
> If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

ServerProxy.system.methodHelp(*name*)

> This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The

documentation string may contain HTML markup.

Changed in version 3.5: Instances of **ServerProxy** support the context manager protocol for closing the underlying transport.

A working example follows. The server code:

```
from xmlrpc.server import SimpleXMLRPCServer

def is_even(n):
    return n % 2 == 0

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(is_even, "is_even")
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client

with xmlrpc.client.ServerProxy("http://localhost:8000/")
    print("3 is even: %s" % str(proxy.is_even(3)))
    print("100 is even: %s" % str(proxy.is_even(100)))
```

DateTime Objects

class xmlrpc.client.DateTime

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8601 time/date string, or a **datetime.datetime** instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

decode(*string*)

Accept a string as the instance's new time value.

encode(*out*)

Write the XML-RPC encoding of this **DateTime** item to the *out* stream object.

It also supports certain of Python's built-in operators through rich comparison and **__repr__()** methods.

A working example follows. The server code:

```
import datetime
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def today():
    today = datetime.datetime.today()
    return xmlrpc.client.DateTime(today)

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(today, "today")
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client
import datetime

proxy = xmlrpc.client.ServerProxy("http://localhost:8000

today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value, "%Y%
print("Today: %s" % converted.strftime("%d.%m.%Y, %H:%M"
```

Binary Objects

class xmlrpc.client.Binary

This class may be initialized from bytes data (which may include NULs). The primary access to the content of a **Binary** object is provided by an attribute:

data

The binary data encapsulated by the **Binary** instance. The data is provided as a **bytes** object.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

decode(*bytes*)

Accept a base64 **bytes** object and decode it as the instance's new data.

encode(*out*)

Write the XML-RPC base 64 encoding of this binary item to the *out* stream object.

The encoded data will have newlines every 76 characters as per **RFC 2045 section 6.8** [https://datatracker.ietf.org/doc/html/rfc2045.html#section-6.8], which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python's built-in operators through **__eq__()** and **__ne__()** methods.

Example usage of the binary objects. We're going to transfer an image over XMLRPC:

```
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
        return xmlrpc.client.Binary(handle.read())

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(python_logo, 'python_logo')
```

```
server.serve_forever()
```

The client gets the image and saves it to a file:

```
import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000
with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
```

Fault Objects

class xmlrpc.client.Fault

A **Fault** object encapsulates the content of an XML-RPC fault tag. Fault objects have the following attributes:

faultCode

An int indicating the fault type.

faultString

A string containing a diagnostic message associated with the fault.

In the following example we're going to intentionally cause a **Fault** by returning a complex type object. The server code:

```
from xmlrpc.server import SimpleXMLRPCServer

# A marshalling error is going to occur because we're re
# complex number
def add(x, y):
    return x+y+0j

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(add, 'add')
```

```
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000
try:
    proxy.add(2, 5)
except xmlrpc.client.Fault as err:
    print("A fault occurred")
    print("Fault code: %d" % err.faultCode)
    print("Fault string: %s" % err.faultString)
```

ProtocolError Objects

class xmlrpc.client.ProtocolError

A **`ProtocolError`** object describes a protocol error in the underlying transport layer (such as a 404 'not found' error if the server named by the URI does not exist). It has the following attributes:

url

The URI or URL that triggered the error.

errcode

The error code.

errmsg

The error message or diagnostic string.

headers

A dict containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we're going to intentionally cause a **`ProtocolError`** by providing an invalid URI:

```
import xmlrpc.client

# create a ServerProxy with a URI that doesn't respond t
proxy = xmlrpc.client.ServerProxy("http://google.com/")

try:
    proxy.some_method()
except xmlrpc.client.ProtocolError as err:
    print("A protocol error occurred")
    print("URL: %s" % err.url)
    print("HTTP/HTTPS headers: %s" % err.headers)
    print("Error code: %d" % err.errcode)
    print("Error message: %s" % err.errmsg)
```

MultiCall Objects

The **`MultiCall`** object provides a way to encapsulate multiple calls to a remote server into a single request 1.

class xmlrpc.client.MultiCall(*server*)

> Create an object used to boxcar method calls. *server* is the eventual target of the call. Calls can be made to the result object, but they will immediately return `None`, and only store the call name and parameters in the **`MultiCall`** object. Calling the object itself causes all stored calls to be transmitted as a single `system.multicall` request. The result of this call is a generator; iterating over this generator yields the individual results.

A usage example of this class follows. The server code:

```
from xmlrpc.server import SimpleXMLRPCServer

def add(x, y):
    return x + y

def subtract(x, y):
    return x - y
```

```
def multiply(x, y):
    return x * y

def divide(x, y):
    return x // y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_multicall_functions()
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000
multicall = xmlrpc.client.MultiCall(proxy)
multicall.add(7, 3)
multicall.subtract(7, 3)
multicall.multiply(7, 3)
multicall.divide(7, 3)
result = multicall()

print("7+3=%d, 7-3=%d, 7*3=%d, 7//3=%d" % tuple(result))
```

Convenience Functions

xmlrpc.client.dumps(*params*, *methodname=None*, *methodresponse=None*, *encoding=None*, *allow_none=False*)

Convert *params* into an XML-RPC request. or into a response if *methodresponse* is true. *params* can be either a tuple of arguments or an instance of the **`Fault`** exception class. If

methodresponse is true, only a single value can be returned, meaning that *params* must be of length 1. *encoding*, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python's **None** value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for *allow_none*.

xmlrpc.client.loads(*data*, *use_datetime*=*False*, *use_builtin_types*=*False*)

Convert an XML-RPC request or response into Python objects, a `(params, methodname)`. *params* is a tuple of argument; *methodname* is a string, or `None` if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a **Fault** exception. The *use_builtin_types* flag can be used to cause date/time values to be presented as **datetime.datetime** objects and binary data to be presented as **bytes** objects; this flag is false by default.

The obsolete *use_datetime* flag is similar to *use_builtin_types* but it applies only to date/time values.

Changed in version 3.3: The *use_builtin_types* flag was added.

Example of Client Usage

```
# simple test program (from the XML-RPC specification)
from xmlrpc.client import ServerProxy, Error

# server = ServerProxy("http://localhost:8000") # local
with ServerProxy("http://betty.userland.com") as proxy:

    print(proxy)

    try:
        print(proxy.examples.getStateName(41))
    except Error as v:
        print("ERROR", v)
```

To access an XML-RPC server through a HTTP proxy, you need to define a custom transport. The following example shows how:

```
import http.client
import xmlrpc.client

class ProxiedTransport(xmlrpc.client.Transport):

    def set_proxy(self, host, port=None, headers=None):
        self.proxy = host, port
        self.proxy_headers = headers

    def make_connection(self, host):
        connection = http.client.HTTPConnection(*self.pr
        connection.set_tunnel(host, headers=self.proxy_h
        self._connection = host, connection
        return connection

transport = ProxiedTransport()
transport.set_proxy('proxy-server', 8080)
server = xmlrpc.client.ServerProxy('http://betty.userlar
print(server.examples.getStateName(41))
```

Example of Client and Server Usage

See SimpleXMLRPCServer Example.

Footnotes

1

This approach has been first presented in a discussion on xmlrpc.com [https://web.archive.org/web/20060624230303/http://www.xmlrpc.com/discuss/msgReader$1208?mode=topic].

`xmlrpc.server` — Basic XML-RPC servers

Source code: Lib/xmlrpc/server.py [https://github.com/python/cpython/tree/3.11/Lib/xmlrpc/server.py]

The `xmlrpc.server` module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using `SimpleXMLRPCServer`, or embedded in a CGI environment, using `CGIXMLRPCRequestHandler`.

Warning

The `xmlrpc.server` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

class xmlrpc.server.SimpleXMLRPCServer(*addr*, *requestHandler=SimpleXMLRPCRequestHandler*, *logRequests=True*, *allow_none=False*, *encoding=None*, *bind_and_activate=True*, *use_builtin_types=False*)

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The *requestHandler* parameter should be a factory for request handler instances; it defaults to `SimpleXMLRPCRequestHandler`. The *addr* and *requestHandler* parameters are passed to the

socketserver.TCPServer constructor. If *logRequests* is true (the default), requests will be logged; setting this parameter to false will turn off logging. The *allow_none* and *encoding* parameters are passed on to **xmlrpc.client** and control the XML-RPC responses that will be returned from the server. The *bind_and_activate* parameter controls whether **server_bind()** and **server_activate()** are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the *allow_reuse_address* class variable before the address is bound. The *use_builtin_types* parameter is passed to the **loads()** function and controls which types are processed when date/times values or binary data are received; it defaults to false.

Changed in version 3.3: The *use_builtin_types* flag was added.

class xmlrpc.server.CGIXMLRPCRequestHandler(*allow_none* = *False*, *encoding* = *None*, *use_builtin_types* = *False*)

Create a new instance to handle XML-RPC requests in a CGI environment. The *allow_none* and *encoding* parameters are passed on to **xmlrpc.client** and control the XML-RPC responses that will be returned from the server. The *use_builtin_types* parameter is passed to the **loads()** function and controls which types are processed when date/times values or binary data are received; it defaults to false.

Changed in version 3.3: The *use_builtin_types* flag was added.

class xmlrpc.server.SimpleXMLRPCRequestHandler

Create a new request handler instance. This request handler supports `POST` requests and modifies logging so that the *logRequests* parameter to the **SimpleXMLRPCServer** constructor parameter is honored.

SimpleXMLRPCServer Objects

The **SimpleXMLRPCServer** class is based on **socketserver.TCPServer** and provides a means of creating

simple, stand alone XML-RPC servers.

SimpleXMLRPCServer.register_function(*function=None*, *name=None*)

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with *function*, otherwise `function.__name__` will be used. *name* is a string, and may contain characters not legal in Python identifiers, including the period character.

This method can also be used as a decorator. When used as a decorator, *name* can only be given as a keyword argument to register *function* under *name*. If no *name* is given, `function.__name__` will be used.

Changed in version 3.7: **`register_function()`** can be used as a decorator.

SimpleXMLRPCServer.register_instance(*instance*, *allow_dotted_names=False*)

Register an object which is used to expose method names which have not been registered using **`register_function()`**. If *instance* contains a **`_dispatch()`** method, it is called with the requested method name and the parameters from the request. Its API is `def _dispatch(self, method, params)` (note that *params* does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as `func(*params)`, expanding the parameter list. The return value from **`_dispatch()`** is returned to the client as the result. If *instance* does not have a **`_dispatch()`** method, it is searched for an attribute matching the name of the requested method.

If the optional *allow_dotted_names* argument is true and the instance does not have a **`_dispatch()`** method, then if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value

found from this search is then called with the parameters from the request, and the return value is passed back to the client.

Warning

Enabling the *allow_dotted_names* option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

SimpleXMLRPCServer.register_introspection_functions()

Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

SimpleXMLRPCServer.register_multicall_functions()

Registers the XML-RPC multicall function system.multicall.

SimpleXMLRPCRequestHandler.rpc_paths

An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 "no such page" HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.

SimpleXMLRPCServer Example

Server code:

```
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler

# Restrict to a particular path.
class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)
```

```
# Create server
with SimpleXMLRPCServer(('localhost', 8000),
                        requestHandler=RequestHandler) a
    server.register_introspection_functions()

    # Register pow() function; this will use the value o
    # pow.__name__ as the name, which is just 'pow'.
    server.register_function(pow)

    # Register a function under a different name
    def adder_function(x, y):
        return x + y
    server.register_function(adder_function, 'add')

    # Register an instance; all the methods of the insta
    # published as XML-RPC methods (in this case, just '
    class MyFuncs:
        def mul(self, x, y):
            return x * y

    server.register_instance(MyFuncs())

    # Run the server's main loop
    server.serve_forever()
```

The following client code will call the methods made available by the preceding server:

```
import xmlrpc.client

s = xmlrpc.client.ServerProxy('http://localhost:8000')
print(s.pow(2,3))  # Returns 2**3 = 8
print(s.add(2,3))  # Returns 5
print(s.mul(5,2))  # Returns 5*2 = 10

# Print list of available methods
print(s.system.listMethods())
```

`register_function()` can also be used as a decorator. The

previous server example can register functions in a decorator way:

```
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler

class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

with SimpleXMLRPCServer(('localhost', 8000),
                        requestHandler=RequestHandler) a
    server.register_introspection_functions()

    # Register pow() function; this will use the value o
    # pow.__name__ as the name, which is just 'pow'.
    server.register_function(pow)

    # Register a function under a different name, using
    # register_function as a decorator. *name* can only
    # as a keyword argument.
    @server.register_function(name='add')
    def adder_function(x, y):
        return x + y

    # Register a function under function.__name__.
    @server.register_function
    def mul(x, y):
        return x * y

    server.serve_forever()
```

The following example included in the `Lib/xmlrpc/server.py` module shows a server allowing dotted names and registering a multicall function.

Warning

Enabling the *allow_dotted_names* option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this example

only within a secure, closed network.

```
import datetime

class ExampleService:
    def getData(self):
        return '42'

    class currentTime:
        @staticmethod
        def getCurrentTime():
            return datetime.datetime.now()

with SimpleXMLRPCServer(("localhost", 8000)) as server:
    server.register_function(pow)
    server.register_function(lambda x,y: x+y, 'add')
    server.register_instance(ExampleService(), allow_dot
    server.register_multicall_functions()
    print('Serving XML-RPC on localhost port 8000')
    try:
        server.serve_forever()
    except KeyboardInterrupt:
        print("\nKeyboard interrupt received, exiting.")
        sys.exit(0)
```

This ExampleService demo can be invoked from the command line:

```
python -m xmlrpc.server
```

The client that interacts with the above server is included in `Lib/xmlrpc/client.py`:

```
server = ServerProxy("http://localhost:8000")

try:
    print(server.currentTime.getCurrentTime())
except Error as v:
    print("ERROR", v)
```

```
multi = MultiCall(server)
multi.getData()
multi.pow(2,9)
multi.add(1,2)
try:
    for response in multi():
        print(response)
except Error as v:
    print("ERROR", v)
```

This client which interacts with the demo XMLRPC server can be invoked as:

```
python -m xmlrpc.client
```

CGIXMLRPCRequestHandler

The **CGIXMLRPCRequestHandler** class can be used to handle XML-RPC requests sent to Python CGI scripts.

CGIXMLRPCRequestHandler.register_function(*function=None*, *name=None*)

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with *function*, otherwise `function.__name__` will be used. *name* is a string, and may contain characters not legal in Python identifiers, including the period character.

This method can also be used as a decorator. When used as a decorator, *name* can only be given as a keyword argument to register *function* under *name*. If no *name* is given, `function.__name__` will be used.

Changed in version 3.7: **register_function()** can be used as a decorator.

CGIXMLRPCRequestHandler.register_instance(*instance*)

Register an object which is used to expose method names which have not been registered using

register_function(). If instance contains a **_dispatch()** method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a **_dispatch()** method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

CGIXMLRPCRequestHandler.register_introspection_functions()

Register the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

CGIXMLRPCRequestHandler.register_multicall_functions()

Register the XML-RPC multicall function `system.multicall`.

CGIXMLRPCRequestHandler.handle_request(*request_text* = *None*)

Handle an XML-RPC request. If *request_text* is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

Example:

```
class MyFuncs:
    def mul(self, x, y):
        return x * y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x,y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
```

```
handler.handle_request()
```

Documenting XMLRPC server

These classes extend the above classes to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using **DocXMLRPCServer**, or embedded in a CGI environment, using **DocCGIXMLRPCRequestHandler**.

class xmlrpc.server.DocXMLRPCServer(*addr*, *requestHandler*=*DocXMLRPCRequestHandler*, *logRequests*=*True*, *allow_none*=*False*, *encoding*=*None*, *bind_and_activate*=*True*, *use_builtin_types*=*True*)

Create a new server instance. All parameters have the same meaning as for **SimpleXMLRPCServer**; *requestHandler* defaults to **DocXMLRPCRequestHandler**.

Changed in version 3.3: The *use_builtin_types* flag was added.

class xmlrpc.server.DocCGIXMLRPCRequestHandler

Create a new instance to handle XML-RPC requests in a CGI environment.

class xmlrpc.server.DocXMLRPCRequestHandler

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the *logRequests* parameter to the **DocXMLRPCServer** constructor parameter is honored.

DocXMLRPCServer Objects

The **DocXMLRPCServer** class is derived from **SimpleXMLRPCServer** and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocXMLRPCServer.set_server_title(*server_title*)

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocXMLRPCServer.set_server_name(*server_name*)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocXMLRPCServer.set_server_documentation(*server_documentation*)

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.

DocCGIXMLRPCRequestHandler

The **`DocCGIXMLRPCRequestHandler`** class is derived from **`CGIXMLRPCRequestHandler`** and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocCGIXMLRPCRequestHandler.set_server_title(*server_title*)

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocCGIXMLRPCRequestHandler.set_server_name(*server_name*)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocCGIXMLRPCRequestHandler.set_server_documentation(*server_documenta*

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.

`ipaddress` — IPv4/IPv6 manipulation library

Source code: Lib/ipaddress.py [https://github.com/python/cpython/tree/3.11/Lib/ipaddress.py]

`ipaddress` provides the capabilities to create, manipulate and operate on IPv4 and IPv6 addresses and networks.

The functions and classes in this module make it straightforward to handle various tasks related to IP addresses, including checking whether or not two hosts are on the same subnet, iterating over all hosts in a particular subnet, checking whether or not a string represents a valid IP address or network definition, and so on.

This is the full module API reference—for an overview and introduction, see An introduction to the ipaddress module.

New in version 3.3.

Convenience factory functions

The `ipaddress` module provides factory functions to conveniently create IP addresses, networks and interfaces:

ipaddress.ip_address(*address*)

Return an `IPv4Address` or `IPv6Address` object depending on the IP address passed as argument. Either IPv4 or IPv6 addresses may be supplied; integers less than `2**32` will be considered to be IPv4 by default. A `ValueError` is raised if *address* does not represent a valid IPv4 or IPv6 address.

```
>>> ipaddress.ip_address('192.168.0.1')
```

```
IPv4Address('192.168.0.1')
>>> ipaddress.ip_address('2001:db8::')
IPv6Address('2001:db8::')
```

ipaddress.ip_network(*address*, *strict*=*True*)

Return an **IPv4Network** or **IPv6Network** object depending on the IP address passed as argument. *address* is a string or integer representing the IP network. Either IPv4 or IPv6 networks may be supplied; integers less than `2**32` will be considered to be IPv4 by default. *strict* is passed to **IPv4Network** or **IPv6Network** constructor. A **ValueError** is raised if *address* does not represent a valid IPv4 or IPv6 address, or if the network has host bits set.

```
>>> ipaddress.ip_network('192.168.0.0/28')
IPv4Network('192.168.0.0/28')
```

ipaddress.ip_interface(*address*)

Return an **IPv4Interface** or **IPv6Interface** object depending on the IP address passed as argument. *address* is a string or integer representing the IP address. Either IPv4 or IPv6 addresses may be supplied; integers less than `2**32` will be considered to be IPv4 by default. A **ValueError** is raised if *address* does not represent a valid IPv4 or IPv6 address.

One downside of these convenience functions is that the need to handle both IPv4 and IPv6 formats means that error messages provide minimal information on the precise error, as the functions don't know whether the IPv4 or IPv6 format was intended. More detailed error reporting can be obtained by calling the appropriate version specific class constructors directly.

IP Addresses

Address objects

The **IPv4Address** and **IPv6Address** objects share a lot of

common attributes. Some attributes that are only meaningful for IPv6 addresses are also implemented by **IPv4Address** objects, in order to make it easier to write code that handles both IP versions correctly. Address objects are hashable, so they can be used as keys in dictionaries.

class ipaddress.IPv4Address(*address*)

Construct an IPv4 address. An **AddressValueError** is raised if *address* is not a valid IPv4 address.

The following constitutes a valid IPv4 address:

1. A string in decimal-dot notation, consisting of four decimal integers in the inclusive range 0–255, separated by dots (e.g. `192.168.0.1`). Each integer represents an octet (byte) in the address. Leading zeroes are not tolerated to prevent confusion with octal notation.
2. An integer that fits into 32 bits.
3. An integer packed into a **bytes** object of length 4 (most significant octet first).

```
>>> ipaddress.IPv4Address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(3232235521)
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(b'\xC0\xA8\x00\x01')
IPv4Address('192.168.0.1')
```

Changed in version 3.8: Leading zeros are tolerated, even in ambiguous cases that look like octal notation.

Changed in version 3.10: Leading zeros are no longer tolerated and are treated as an error. IPv4 address strings are now parsed as strict as glibc **inet_pton()**.

Changed in version 3.9.5: The above change was also included in Python 3.9 starting with version 3.9.5.

Changed in version 3.8.12: The above change was also included in Python 3.8 starting with version 3.8.12.

version

The appropriate version number: `4` for IPv4, `6` for IPv6.

max_prefixlen

The total number of bits in the address representation for this version: `32` for IPv4, `128` for IPv6.

The prefix defines the number of leading bits in an address that are compared to determine whether or not an address is part of a network.

compressed

exploded

The string representation in dotted decimal notation. Leading zeroes are never included in the representation.

As IPv4 does not define a shorthand notation for addresses with octets set to zero, these two attributes are always the same as `str(addr)` for IPv4 addresses. Exposing these attributes makes it easier to write display code that can handle both IPv4 and IPv6 addresses.

packed

The binary representation of this address - a **`bytes`** object of the appropriate length (most significant octet first). This is 4 bytes for IPv4 and 16 bytes for IPv6.

reverse_pointer

The name of the reverse DNS PTR record for the IP address, e.g.:

```
>>> ipaddress.ip_address("127.0.0.1").reverse_p
'1.0.0.127.in-addr.arpa'
>>> ipaddress.ip_address("2001:db8::1").reverse
```

'1.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.

This is the name that could be used for performing a PTR lookup, not the resolved hostname itself.

New in version 3.5.

is_multicast

`True` if the address is reserved for multicast use. See **RFC 3171** [https://datatracker.ietf.org/doc/html/rfc3171.html] (for IPv4) or **RFC 2373** [https://datatracker.ietf.org/doc/html/rfc2373.html] (for IPv6).

is_private

`True` if the address is allocated for private networks. See iana-ipv4-special-registry [https://www.iana.org/assignments/iana-ipv4-special-registry/iana-ipv4-special-registry.xhtml] (for IPv4) or iana-ipv6-special-registry [https://www.iana.org/assignments/iana-ipv6-special-registry/iana-ipv6-special-registry.xhtml] (for IPv6).

is_global

`True` if the address is allocated for public networks. See iana-ipv4-special-registry [https://www.iana.org/assignments/iana-ipv4-special-registry/iana-ipv4-special-registry.xhtml] (for IPv4) or iana-ipv6-special-registry [https://www.iana.org/assignments/iana-ipv6-special-registry/iana-ipv6-special-registry.xhtml] (for IPv6).

New in version 3.4.

is_unspecified

`True` if the address is unspecified. See **RFC 5735** [https://datatracker.ietf.org/doc/html/rfc5735.html] (for IPv4) or **RFC 2373** [https://datatracker.ietf.org/doc/html/rfc2373.html] (for IPv6).

is_reserved

`True` if the address is otherwise IETF reserved.

is_loopback

`True` if this is a loopback address. See **RFC 3330** [https://datatracker.ietf.org/doc/html/rfc3330.html] (for IPv4) or **RFC 2373** [https://datatracker.ietf.org/doc/html/rfc2373.html] (for IPv6).

is_link_local

`True` if the address is reserved for link-local usage. See **RFC 3927** [https://datatracker.ietf.org/doc/html/rfc3927.html].

IPv4Address._format_(*fmt*)

Returns a string representation of the IP address, controlled by an explicit format string. *fmt* can be one of the following: `'s'`, the default option, equivalent to **`str()`**, `'b'` for a zero-padded binary string, `'X'` or `'x'` for an uppercase or lowercase hexadecimal representation, or `'n'`, which is equivalent to `'b'` for IPv4 addresses and `'x'` for IPv6. For binary and hexadecimal representations, the form specifier `'#'` and the grouping option `'_'` are available. `__format__` is used by `format`, `str.format` and f-strings.

```
>>> format(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> '{:#b}'.format(ipaddress.IPv4Address('192.168.0
'0b11000000101010000000000000000001'
>>> f'{ipaddress.IPv6Address("2001:db8::1000"):s}'
'2001:db8::1000'
>>> format(ipaddress.IPv6Address('2001:db8::1000'),
'2001_0DB8_0000_0000_0000_0000_0000_1000'
>>> '{:#_n}'.format(ipaddress.IPv6Address('2001:db8
'0x2001_0db8_0000_0000_0000_0000_0000_1000'
```

New in version 3.9.

class ipaddress.IPv6Address(*address*)

Construct an IPv6 address. An **`AddressValueError`** is raised if *address* is not a valid IPv6 address.

The following constitutes a valid IPv6 address:

1. A string consisting of eight groups of four hexadecimal digits, each group representing 16 bits. The groups are separated by colons. This describes an *exploded* (longhand) notation. The string can also be *compressed* (shorthand notation) by various means. See **RFC 4291** [https://datatracker.ietf.org/doc/html/rfc4291.html] for details. For example, `"0000:0000:0000:0000:0000:0abc:0007:0def"` can be compressed to `"::abc:7:def"`.

   Optionally, the string may also have a scope zone ID, expressed with a suffix `%scope_id`. If present, the scope ID must be non-empty, and may not contain `%`. See **RFC 4007** [https://datatracker.ietf.org/doc/html/rfc4007.html] for details. For example, `fe80::1234%1` might identify address `fe80::1234` on the first link of the node.

2. An integer that fits into 128 bits.

3. An integer packed into a **`bytes`** object of length 16, big-endian.

```
>>> ipaddress.IPv6Address('2001:db8::1000')
IPv6Address('2001:db8::1000')
>>> ipaddress.IPv6Address('ff02::5678%1')
IPv6Address('ff02::5678%1')
```

compressed

The short form of the address representation, with leading zeroes in groups omitted and the longest sequence of groups consisting entirely of zeroes collapsed to a single empty group.

This is also the value returned by `str(addr)` for IPv6 addresses.

exploded

The long form of the address representation, with all leading zeroes and groups consisting entirely of zeroes included.

For the following attributes and methods, see the corresponding documentation of the **IPv4Address** class:

packed

reverse_pointer

version

max_prefixlen

is_multicast

is_private

is_global

is_unspecified

is_reserved

is_loopback

is_link_local

New in version 3.4: is_global

is_site_local

`True` if the address is reserved for site-local usage. Note that the site-local address space has been deprecated by **RFC 3879** [https://datatracker.ietf.org/doc/html/rfc3879.html]. Use **is_private** to test if this address is in the space of unique local addresses as defined by **RFC 4193** [https://datatracker.ietf.org/doc/html/rfc4193.html].

ipv4_mapped

For addresses that appear to be IPv4 mapped addresses (starting with `::FFFF/96`), this property will report the embedded IPv4 address. For any other address, this property will be `None`.

scope_id

For scoped addresses as defined by **RFC 4007** [https://datatracker.ietf.org/doc/html/rfc4007.html], this property identifies the particular zone of the address's scope that the address belongs to, as a string. When no scope zone is specified, this property will be `None`.

sixtofour

For addresses that appear to be 6to4 addresses (starting with `2002::/16`) as defined by **RFC 3056** [https://datatracker.ietf.org/doc/html/rfc3056.html], this property will report the embedded IPv4 address. For any other address, this property will be `None`.

teredo

For addresses that appear to be Teredo addresses (starting with `2001::/32`) as defined by **RFC 4380** [https://datatracker.ietf.org/doc/html/rfc4380.html], this property will report the embedded `(server, client)` IP address pair. For any other address, this property will be `None`.

IPv6Address._format_(*fmt*)

Refer to the corresponding method documentation in **`IPv4Address`**.

New in version 3.9.

Conversion to Strings and Integers

To interoperate with networking interfaces such as the socket module, addresses must be converted to strings or integers. This is

handled using the `str()` and `int()` builtin functions:

```
>>> str(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> int(ipaddress.IPv4Address('192.168.0.1'))
3232235521
>>> str(ipaddress.IPv6Address('::1'))
'::1'
>>> int(ipaddress.IPv6Address('::1'))
1
```

Note that IPv6 scoped addresses are converted to integers without scope zone ID.

Operators

Address objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

Comparison operators

Address objects can be compared with the usual set of comparison operators. Same IPv6 addresses with different scope zone IDs are not equal. Some examples:

```
>>> IPv4Address('127.0.0.2') > IPv4Address('127.0.0.1')
True
>>> IPv4Address('127.0.0.2') == IPv4Address('127.0.0.1')
False
>>> IPv4Address('127.0.0.2') != IPv4Address('127.0.0.1')
True
>>> IPv6Address('fe80::1234') == IPv6Address('fe80::1234
False
>>> IPv6Address('fe80::1234%1') != IPv6Address('fe80::12
True
```

Arithmetic operators

Integers can be added to or subtracted from address objects. Some examples:

```
>>> IPv4Address('127.0.0.2') + 3
IPv4Address('127.0.0.5')
>>> IPv4Address('127.0.0.2') - 3
IPv4Address('126.255.255.255')
>>> IPv4Address('255.255.255.255') + 1
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ipaddress.AddressValueError: 4294967296 (>= 2**32) is no
```

IP Network definitions

The **`IPv4Network`** and **`IPv6Network`** objects provide a mechanism for defining and inspecting IP network definitions. A network definition consists of a *mask* and a *network address*, and as such defines a range of IP addresses that equal the network address when masked (binary AND) with the mask. For example, a network definition with the mask `255.255.255.0` and the network address `192.168.1.0` consists of IP addresses in the inclusive range `192.168.1.0` to `192.168.1.255`.

Prefix, net mask and host mask

There are several equivalent ways to specify IP network masks. A *prefix* `/<nbits>` is a notation that denotes how many high-order bits are set in the network mask. A *net mask* is an IP address with some number of high-order bits set. Thus the prefix `/24` is equivalent to the net mask `255.255.255.0` in IPv4, or `ffff:ff00::` in IPv6. In addition, a *host mask* is the logical inverse of a *net mask*, and is sometimes used (for example in Cisco access control lists) to denote a network mask. The host mask equivalent to `/24` in IPv4 is `0.0.0.255`.

Network objects

All attributes implemented by address objects are implemented by network objects as well. In addition, network objects implement

additional attributes. All of these are common between **IPv4Network** and **IPv6Network**, so to avoid duplication they are only documented for **IPv4Network**. Network objects are hashable, so they can be used as keys in dictionaries.

class ipaddress.IPv4Network(*address*, *strict*=*True*)

Construct an IPv4 network definition. *address* can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (`/`). The IP address is the network address, and the mask can be either a single number, which means it's a *prefix*, or a string representation of an IPv4 address. If it's the latter, the mask is interpreted as a *net mask* if it starts with a non-zero field, or as a *host mask* if it starts with a zero field, with the single exception of an all-zero mask which is treated as a *net mask*. If no mask is provided, it's considered to be `/32`.

   For example, the following *address* specifications are equivalent: `192.168.1.0/24`, `192.168.1.0/255.255.255.0` and `192.168.1.0/0.0.0.255`.

2. An integer that fits into 32 bits. This is equivalent to a single-address network, with the network address being *address* and the mask being `/32`.

3. An integer packed into a **bytes** object of length 4, big-endian. The interpretation is similar to an integer *address*.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 32-bits integer, a 4-bytes packed integer, or an existing IPv4Address object; and the netmask is either an integer representing the prefix length (e.g. `24`) or a string representing the prefix mask (e.g. `255.255.255.0`).

An **AddressValueError** is raised if *address* is not a valid IPv4 address. A **NetmaskValueError** is raised if the mask is not valid for an IPv4 address.

If *strict* is `True` and host bits are set in the supplied address, then **ValueError** is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

Unless stated otherwise, all network methods accepting other network/address objects will raise **TypeError** if the argument's IP version is incompatible to `self`.

Changed in version 3.5: Added the two-tuple form for the *address* constructor parameter.

version

max_prefixlen

Refer to the corresponding attribute documentation in **IPv4Address**.

is_multicast

is_private

is_unspecified

is_reserved

is_loopback

is_link_local

These attributes are true for the network as a whole if they are true for both the network address and the broadcast address.

network_address

The network address for the network. The network address and the prefix length together uniquely define a

network.

broadcast_address

The broadcast address for the network. Packets sent to the broadcast address should be received by every host on the network.

hostmask

The host mask, as an **`IPv4Address`** object.

netmask

The net mask, as an **`IPv4Address`** object.

with_prefixlen

compressed

exploded

A string representation of the network, with the mask in prefix notation.

`with_prefixlen` and `compressed` are always the same as `str(network)`. `exploded` uses the exploded form the network address.

with_netmask

A string representation of the network, with the mask in net mask notation.

with_hostmask

A string representation of the network, with the mask in host mask notation.

num_addresses

The total number of addresses in the network.

prefixlen

Length of the network prefix, in bits.

hosts()

Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the network address itself and the network broadcast address. For networks with a mask length of 31, the network address and network broadcast address are also included in the result. Networks with a mask of 32 will return a list containing the single host address.

```
>>> list(ip_network('192.0.2.0/29').hosts())
[IPv4Address('192.0.2.1'), IPv4Address('192.0.2
 IPv4Address('192.0.2.3'), IPv4Address('192.0.2
 IPv4Address('192.0.2.5'), IPv4Address('192.0.2
>>> list(ip_network('192.0.2.0/31').hosts())
[IPv4Address('192.0.2.0'), IPv4Address('192.0.2
>>> list(ip_network('192.0.2.1/32').hosts())
[IPv4Address('192.0.2.1')]
```

overlaps(*other*)

`True` if this network is partly or wholly contained in *other* or *other* is wholly contained in this network.

address_exclude(*network*)

Computes the network definitions resulting from removing the given *network* from this one. Returns an iterator of network objects. Raises **`ValueError`** if *network* is not completely contained in this network.

```
>>> n1 = ip_network('192.0.2.0/28')
>>> n2 = ip_network('192.0.2.1/32')
>>> list(n1.address_exclude(n2))
[IPv4Network('192.0.2.8/29'), IPv4Network('192.
 IPv4Network('192.0.2.2/31'), IPv4Network('192.
```

subnets(*prefixlen_diff=1*, *new_prefix=None*)

The subnets that join to make the current network definition, depending on the argument values. *prefixlen_diff* is the amount our prefix length should be increased by. *new_prefix* is the desired new prefix of the subnets; it must be larger than our prefix. One and only one of *prefixlen_diff* and *new_prefix* must be set. Returns an iterator of network objects.

```
>>> list(ip_network('192.0.2.0/24').subnets())
[IPv4Network('192.0.2.0/25'), IPv4Network('192.
>>> list(ip_network('192.0.2.0/24').subnets(pre
[IPv4Network('192.0.2.0/26'), IPv4Network('192.
 IPv4Network('192.0.2.128/26'), IPv4Network('19
>>> list(ip_network('192.0.2.0/24').subnets(new
[IPv4Network('192.0.2.0/26'), IPv4Network('192.
 IPv4Network('192.0.2.128/26'), IPv4Network('19
>>> list(ip_network('192.0.2.0/24').subnets(new
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
    raise ValueError('new prefix must be longer
ValueError: new prefix must be longer
>>> list(ip_network('192.0.2.0/24').subnets(new
[IPv4Network('192.0.2.0/25'), IPv4Network('192.
```

supernet(*prefixlen_diff=1*, *new_prefix=None*)

The supernet containing this network definition, depending on the argument values. *prefixlen_diff* is the amount our prefix length should be decreased by. *new_prefix* is the desired new prefix of the supernet; it must be smaller than our prefix. One and only one of *prefixlen_diff* and *new_prefix* must be set. Returns a single network object.

```
>>> ip_network('192.0.2.0/24').supernet()
IPv4Network('192.0.2.0/23')
>>> ip_network('192.0.2.0/24').supernet(prefixl
IPv4Network('192.0.0.0/22')
>>> ip_network('192.0.2.0/24').supernet(new_pre
IPv4Network('192.0.0.0/20')
```

subnet_of(*other*)

Return `True` if this network is a subnet of *other*.

```
>>> a = ip_network('192.168.1.0/24')
>>> b = ip_network('192.168.1.128/30')
>>> b.subnet_of(a)
True
```

New in version 3.7.

supernet_of(*other*)

Return `True` if this network is a supernet of *other*.

```
>>> a = ip_network('192.168.1.0/24')
>>> b = ip_network('192.168.1.128/30')
>>> a.supernet_of(b)
True
```

New in version 3.7.

compare_networks(*other*)

Compare this network to *other*. In this comparison only the network addresses are considered; host bits aren't. Returns either `-1`, `0` or `1`.

```
>>> ip_network('192.0.2.1/32').compare_networks
-1
>>> ip_network('192.0.2.1/32').compare_networks
1
>>> ip_network('192.0.2.1/32').compare_networks
0
```

Deprecated since version 3.7: It uses the same ordering and comparison algorithm as "<", "==", and ">"

class ipaddress.IPv6Network(*address*, *strict=True*)

Construct an IPv6 network definition. *address* can be one of the following:

1. A string consisting of an IP address and an optional prefix length, separated by a slash (`/`). The IP address is the network address, and the prefix length must be a single number, the *prefix*. If no prefix length is provided, it's considered to be `/128`.

   Note that currently expanded netmasks are not supported. That means `2001:db00::0/24` is a valid argument while `2001:db00::0/ffff:ff00::` is not.

2. An integer that fits into 128 bits. This is equivalent to a single-address network, with the network address being *address* and the mask being `/128`.

3. An integer packed into a **`bytes`** object of length 16, big-endian. The interpretation is similar to an integer *address*.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 128-bits integer, a 16-bytes packed integer, or an existing IPv6Address object; and the netmask is an integer representing the prefix length.

An **`AddressValueError`** is raised if *address* is not a valid IPv6 address. A **`NetmaskValueError`** is raised if the mask is not valid for an IPv6 address.

If *strict* is `True` and host bits are set in the supplied address, then **`ValueError`** is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

Changed in version 3.5: Added the two-tuple form for the *address* constructor parameter.

version

hosts()

Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the Subnet-Router anycast address. For networks with a mask length of

127, the Subnet-Router anycast address is also included in the result. Networks with a mask of 128 will return a list containing the single host address.

overlaps(*other*)

address_exclude(*network*)

subnets(*prefixlen_diff=1*, *new_prefix=None*)

supernet(*prefixlen_diff=1*, *new_prefix=None*)

subnet_of(*other*)

supernet_of(*other*)

compare_networks(*other*)

Refer to the corresponding attribute documentation in **IPv4Network**.

is_site_local

These attribute is true for the network as a whole if it is true for both the network address and the broadcast address.

Operators

Network objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

Logical operators

Network objects can be compared with the usual set of logical operators. Network objects are ordered first by network address, then by net mask.

Iteration

Network objects can be iterated to list all the addresses belonging to the network. For iteration, *all* hosts are returned, including unusable hosts (for usable hosts, use the `hosts()` method). An example:

```
>>> for addr in IPv4Network('192.0.2.0/28'):
...     addr
...
IPv4Address('192.0.2.0')
IPv4Address('192.0.2.1')
IPv4Address('192.0.2.2')
IPv4Address('192.0.2.3')
IPv4Address('192.0.2.4')
IPv4Address('192.0.2.5')
IPv4Address('192.0.2.6')
IPv4Address('192.0.2.7')
IPv4Address('192.0.2.8')
IPv4Address('192.0.2.9')
IPv4Address('192.0.2.10')
IPv4Address('192.0.2.11')
IPv4Address('192.0.2.12')
IPv4Address('192.0.2.13')
IPv4Address('192.0.2.14')
IPv4Address('192.0.2.15')
```

Networks as containers of addresses

Network objects can act as containers of addresses. Some examples:

```
>>> IPv4Network('192.0.2.0/28')[0]
IPv4Address('192.0.2.0')
>>> IPv4Network('192.0.2.0/28')[15]
IPv4Address('192.0.2.15')
>>> IPv4Address('192.0.2.6') in IPv4Network('192.0.2.0/2
True
>>> IPv4Address('192.0.3.6') in IPv4Network('192.0.2.0/2
False
```

Interface objects

Interface objects are hashable, so they can be used as keys in dictionaries.

class ipaddress.IPv4Interface(*address*)

Construct an IPv4 interface. The meaning of *address* is as in the constructor of **IPv4Network**, except that arbitrary host addresses are always accepted.

IPv4Interface is a subclass of **IPv4Address**, so it inherits all the attributes from that class. In addition, the following attributes are available:

ip

The address (**IPv4Address**) without network information.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.ip
IPv4Address('192.0.2.5')
```

network

The network (**IPv4Network**) this interface belongs to.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.network
IPv4Network('192.0.2.0/24')
```

with_prefixlen

A string representation of the interface with the mask in prefix notation.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_prefixlen
'192.0.2.5/24'
```

with_netmask

A string representation of the interface with the network as a net mask.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_netmask
'192.0.2.5/255.255.255.0'
```

with_hostmask

A string representation of the interface with the network as a host mask.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_hostmask
'192.0.2.5/0.0.0.255'
```

class ipaddress.IPv6Interface(*address*)

Construct an IPv6 interface. The meaning of *address* is as in the constructor of **IPv6Network**, except that arbitrary host addresses are always accepted.

IPv6Interface is a subclass of **IPv6Address**, so it inherits all the attributes from that class. In addition, the following attributes are available:

ip

network

with_prefixlen

with_netmask

with_hostmask

Refer to the corresponding attribute documentation in **IPv4Interface**.

Operators

Interface objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

Logical operators

Interface objects can be compared with the usual set of logical operators.

For equality comparison (== and !=), both the IP address and network must be the same for the objects to be equal. An interface will not compare equal to any address or network object.

For ordering (<, >, etc) the rules are different. Interface and address objects with the same IP version can be compared, and the address objects will always sort before the interface objects. Two interface objects are first compared by their networks and, if those are the same, then by their IP addresses.

Other Module Level Functions

The module also provides the following module level functions:

ipaddress.v4_int_to_packed(*address*)

Represent an address as 4 packed bytes in network (big-endian) order. *address* is an integer representation of an IPv4 IP address. A **ValueError** is raised if the integer is negative or too large to be an IPv4 IP address.

```
>>> ipaddress.ip_address(3221225985)
IPv4Address('192.0.2.1')
>>> ipaddress.v4_int_to_packed(3221225985)
b'\xc0\x00\x02\x01'
```

ipaddress.v6_int_to_packed(*address*)

Represent an address as 16 packed bytes in network (big-endian) order. *address* is an integer representation of an IPv6 IP address. A **ValueError** is raised if the integer is negative or too large to be an IPv6 IP address.

ipaddress.summarize_address_range(*first*, *last*)

Return an iterator of the summarized network range given the first and last IP addresses. *first* is the first **IPv4Address** or **IPv6Address** in the range and *last* is the last **IPv4Address** or **IPv6Address** in the range. A **TypeError** is raised if *first* or *last* are not IP addresses or are not of the same version. A **ValueError** is raised if *last* is not greater than *first* or if *first* address version is not 4 or 6.

```
>>> [ipaddr for ipaddr in ipaddress.summarize_addre
...     ipaddress.IPv4Address('192.0.2.0'),
...     ipaddress.IPv4Address('192.0.2.130'))]
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.
```

ipaddress.collapse_addresses(*addresses*)

Return an iterator of the collapsed **IPv4Network** or **IPv6Network** objects. *addresses* is an iterator of **IPv4Network** or **IPv6Network** objects. A **TypeError** is raised if *addresses* contains mixed version objects.

```
>>> [ipaddr for ipaddr in
... ipaddress.collapse_addresses([ipaddress.IPv4Net
... ipaddress.IPv4Network('192.0.2.128/25')])]
[IPv4Network('192.0.2.0/24')]
```

ipaddress.get_mixed_type_key(*obj*)

Return a key suitable for sorting between networks and addresses. Address and Network objects are not sortable by default; they're fundamentally different, so the expression:

```
IPv4Address('192.0.2.0') <= IPv4Network('192.0.2.0/
```

doesn't make sense. There are some times however, where you may wish to have **ipaddress** sort these anyway. If you need to do this, you can use this function as the *key* argument to **sorted()**.

obj is either a network or address object.

Custom Exceptions

To support more specific error reporting from class constructors, the module defines the following exceptions:

exception ipaddress.AddressValueError(*ValueError*)

Any value error related to the address.

exception ipaddress.NetmaskValueError(*ValueError*)

Any value error related to the net mask.

Multimedia Services

The modules described in this chapter implement various algorithms or interfaces that are mainly useful for multimedia applications. They are available at the discretion of the installation. Here's an overview:

- **wave** — Read and write WAV files
  - Wave_read Objects
  - Wave_write Objects
- **colorsys** — Conversions between color systems

`wave` — Read and write WAV files

Source code: Lib/wave.py [https://github.com/python/cpython/tree/3.11/Lib/wave.py]

The `wave` module provides a convenient interface to the WAV sound format. Only files using `WAVE_FORMAT_PCM` are supported. Note that this does not include files using `WAVE_FORMAT_EXTENSIBLE` even if the subformat is PCM.

The `wave` module defines the following function and exception:

wave.open(*file*, *mode*=*None*)

If *file* is a string, open the file by that name, otherwise treat it as a file-like object. *mode* can be:

`'rb'`
Read only mode.

`'wb'`
Write only mode.

Note that it does not allow read/write WAV files.

A *mode* of `'rb'` returns a **`Wave_read`** object, while a *mode* of `'wb'` returns a **`Wave_write`** object. If *mode* is omitted and a file-like object is passed as *file*, `file.mode` is used as the default value for *mode*.

If you pass in a file-like object, the wave object will not close it when its **`close()`** method is called; it is the caller's responsibility to close the file object.

The **`open()`** function may be used in a **`with`** statement.

When the **with** block completes, the **Wave_read.close()** or **Wave_write.close()** method is called.

Changed in version 3.4: Added support for unseekable files.

exception wave.Error

An error raised when something is impossible because it violates the WAV specification or hits an implementation deficiency.

Wave_read Objects

Wave_read objects, as returned by **open()**, have the following methods:

Wave_read.close()

Close the stream if it was opened by **wave**, and make the instance unusable. This is called automatically on object collection.

Wave_read.getnchannels()

Returns number of audio channels (`1` for mono, `2` for stereo).

Wave_read.getsampwidth()

Returns sample width in bytes.

Wave_read.getframerate()

Returns sampling frequency.

Wave_read.getnframes()

Returns number of audio frames.

Wave_read.getcomptype()

Returns compression type (`'NONE'` is the only supported type).

Wave_read.getcompname()

Human-readable version of **`getcomptype()`**. Usually `'not compressed'` parallels `'NONE'`.

Wave_read.getparams()

Returns a **`namedtuple()`** `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, equivalent to output of the **`get*()`** methods.

Wave_read.readframes(*n*)

Reads and returns at most *n* frames of audio, as a **`bytes`** object.

Wave_read.rewind()

Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the **`aifc`** module, and don't do anything interesting.

Wave_read.getmarkers()

Returns `None`.

Wave_read.getmark(*id*)

Raise an error.

The following two methods define a term "position" which is compatible between them, and is otherwise implementation dependent.

Wave_read.setpos(*pos*)

Set the file pointer to the specified position.

Wave_read.tell()

Return current file pointer position.

Wave_write Objects

For seekable output streams, the `wave` header will automatically be updated to reflect the number of frames actually written. For unseekable streams, the *nframes* value must be accurate when the first frame data is written. An accurate *nframes* value can be achieved either by calling **`setnframes()`** or **`setparams()`** with the number of frames that will be written before **`close()`** is called and then using **`writeframesraw()`** to write the frame data, or by calling **`writeframes()`** with all of the frame data to be written. In the latter case **`writeframes()`** will calculate the number of frames in the data and set *nframes* accordingly before writing the frame data.

Wave_write objects, as returned by **`open()`**, have the following methods:

Changed in version 3.4: Added support for unseekable files.

Wave_write.close()

Make sure *nframes* is correct, and close the file if it was opened by **`wave`**. This method is called upon object collection. It will raise an exception if the output stream is not seekable and *nframes* does not match the number of frames actually written.

Wave_write.setnchannels(*n*)

Set the number of channels.

Wave_write.setsampwidth(*n*)

Set the sample width to *n* bytes.

Wave_write.setframerate(*n*)

Set the frame rate to *n*.

Changed in version 3.2: A non-integral input to this method is rounded to the nearest integer.

Wave_write.setnframes(*n*)

Set the number of frames to *n*. This will be changed later if the number of frames actually written is different (this update attempt will raise an error if the output stream is not seekable).

Wave_write.setcomptype(*type*, *name*)

Set the compression type and description. At the moment, only compression type `NONE` is supported, meaning no compression.

Wave_write.setparams(*tuple*)

The *tuple* should be `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, with values valid for the **`set*()`** methods. Sets all parameters.

Wave_write.tell()

Return current position in the file, with the same disclaimer for the **`Wave_read.tell()`** and **`Wave_read.setpos()`** methods.

Wave_write.writeframesraw(*data*)

Write audio frames, without correcting *nframes*.

Changed in version 3.4: Any bytes-like object is now accepted.

Wave_write.writeframes(*data*)

Write audio frames and make sure *nframes* is correct. It will raise an error if the output stream is not seekable and the total number of frames that have been written after *data* has been written does not match the previously set value for *nframes*.

Changed in version 3.4: Any bytes-like object is now accepted.

Note that it is invalid to set any parameters after calling **`writeframes()`** or **`writeframesraw()`**, and any attempt to do

so will raise **wave.Error**.

`colorsys` — Conversions between color systems

Source code: Lib/colorsys.py [https://github.com/python/cpython/tree/3.11/Lib/colorsys.py]

The `colorsys` module defines bidirectional conversions of color values between colors expressed in the RGB (Red Green Blue) color space used in computer monitors and three other coordinate systems: YIQ, HLS (Hue Lightness Saturation) and HSV (Hue Saturation Value). Coordinates in all of these color spaces are floating point values. In the YIQ space, the Y coordinate is between 0 and 1, but the I and Q coordinates can be positive or negative. In all other spaces, the coordinates are all between 0 and 1.

See also

More information about color spaces can be found at https://poynton.ca/ColorFAQ.html and https://www.cambridgeincolour.com/tutorials/color-spaces.htm.

The `colorsys` module defines the following functions:

colorsys.rgb_to_yiq(*r*, *g*, *b*)

Convert the color from RGB coordinates to YIQ coordinates.

colorsys.yiq_to_rgb(*y*, *i*, *q*)

Convert the color from YIQ coordinates to RGB coordinates.

colorsys.rgb_to_hls(*r*, *g*, *b*)

Convert the color from RGB coordinates to HLS coordinates.

colorsys.hls_to_rgb(*h*, *l*, *s*)

Convert the color from HLS coordinates to RGB coordinates.

colorsys.rgb_to_hsv(*r*, *g*, *b*)

Convert the color from RGB coordinates to HSV coordinates.

colorsys.hsv_to_rgb(*h*, *s*, *v*)

Convert the color from HSV coordinates to RGB coordinates.

Example:

```
>>> import colorsys
>>> colorsys.rgb_to_hsv(0.2, 0.4, 0.4)
(0.5, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.5, 0.5, 0.4)
(0.2, 0.4, 0.4)
```

Internationalization

The modules described in this chapter help you write software that is independent of language and locale by providing mechanisms for selecting a language to be used in program messages or by tailoring output to match local conventions.

The list of modules described in this chapter is:

- **`gettext`** — Multilingual internationalization services
  - GNU **gettext** API
  - Class-based API
    - The **`NullTranslations`** class
    - The **`GNUTranslations`** class
    - Solaris message catalog support
    - The Catalog constructor
  - Internationalizing your programs and modules
    - Localizing your module
    - Localizing your application
    - Changing languages on the fly
    - Deferred translations
  - Acknowledgements
- **`locale`** — Internationalization services
  - Background, details, hints, tips and caveats
  - For extension writers and programs that embed Python
  - Access to message catalogs

`gettext` — Multilingual internationalization services

Source code: Lib/gettext.py [https://github.com/python/cpython/tree/3.11/Lib/gettext.py]

The `gettext` module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU **gettext** message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.

GNU gettext API

The `gettext` module defines the following API, which is very similar to the GNU **gettext** API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

gettext.bindtextdomain(*domain*, *localedir*=*None*)

Bind the *domain* to the locale directory *localedir*. More concretely, `gettext` will look for binary `.mo` files for the given domain using the path (on Unix): `localedir/language/LC_MESSAGES/domain.mo`, where *language* is searched for in the environment variables **LANGUAGE**,

LC_ALL, **LC_MESSAGES**, and **LANG** respectively.

If *localedir* is omitted or `None`, then the current binding for *domain* is returned. 1

gettext.textdomain(*domain=None*)

Change or query the current global domain. If *domain* is `None`, then the current global domain is returned, otherwise the global domain is set to *domain*, which is returned.

gettext.gettext(*message*)

Return the localized translation of *message*, based on the current global domain, language, and locale directory. This function is usually aliased as **_()** in the local namespace (see examples below).

gettext.dgettext(*domain*, *message*)

Like **gettext()**, but look the message up in the specified *domain*.

gettext.ngettext(*singular*, *plural*, *n*)

Like **gettext()**, but consider plural forms. If a translation is found, apply the plural formula to *n*, and return the resulting message (some languages have more than two plural forms). If no translation is found, return *singular* if *n* is 1; return *plural* otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable *n*; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation [https://www.gnu.org/software/gettext/manual/gettext.html] for the precise syntax to be used in `.po` files and the formulas for a variety of languages.

gettext.dngettext(*domain*, *singular*, *plural*, *n*)

Like **ngettext()**, but look the message up in the specified *domain*.

gettext.pgettext(*context*, *message*)

gettext.dpgettext(*domain*, *context*, *message*)

gettext.npgettext(*context*, *singular*, *plural*, *n*)

gettext.dnpgettext(*domain*, *context*, *singular*, *plural*, *n*)

Similar to the corresponding functions without the `p` in the prefix (that is, **`gettext()`**, **`dgettext()`**, **`ngettext()`**, **`dngettext()`**), but the translation is restricted to the given message *context*.

New in version 3.8.

Note that GNU **gettext** also defines a **`dcgettext()`** method, but this was deemed not useful and so it is currently unimplemented.

Here's an example of typical usage for this API:

```
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my/lar
gettext.textdomain('myapplication')
_ = gettext.gettext
# ...
print(_('This is a translatable string.'))
```

Class-based API

The class-based API of the **`gettext`** module gives you more flexibility and greater convenience than the GNU **gettext** API. It is the recommended way of localizing your Python applications and modules. **`gettext`** defines a **`GNUTranslations`** class which implements the parsing of GNU `.mo` format files, and has methods for returning strings. Instances of this class can also install themselves in the built-in namespace as the function **`_()`**.

gettext.find(*domain*, *localedir*=*None*, *languages*=*None*, *all*=*False*)

This function implements the standard `.mo` file search

algorithm. It takes a *domain*, identical to what **textdomain()** takes. Optional *localedir* is as in **bindtextdomain()**. Optional *languages* is a list of strings, where each string is a language code.

If *localedir* is not given, then the default system locale directory is used. 2 If *languages* is not given, then the following environment variables are searched: **LANGUAGE**, **LC_ALL**, **LC_MESSAGES**, and **LANG**. The first one returning a non-empty value is used for the *languages* variable. The environment variables should contain a colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

find() then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

localedir/*language*/LC_MESSAGES/*domain*.mo

The first such file name that exists is returned by **find()**. If no such file is found, then None is returned. If *all* is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

gettext.translation(*domain*, *localedir*=*None*, *languages*=*None*, *class_*=*None*, *fallback*=*False*)

Return a ***Translations** instance based on the *domain*, *localedir*, and *languages*, which are first passed to **find()** to get a list of the associated .mo file paths. Instances with identical .mo file names are cached. The actual class instantiated is *class_* if provided, otherwise **GNUTranslations**. The class's constructor must take a single file object argument. If provided, *codeset* will change the charset used to encode translated strings in the **lgettext()** and **lngettext()** methods.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, **copy.copy()** is used to clone each translation object from the cache; the

actual instance data is still shared with the cache.

If no `.mo` file is found, this function raises **OSError** if *fallback* is false (which is the default), and returns a **NullTranslations** instance if *fallback* is true.

Changed in version 3.3: **IOError** used to be raised instead of **OSError**.

Changed in version 3.11: codeset parameter is removed.

gettext.install(*domain*, *localedir*=*None*, *, *names*=*None*)

This installs the function **_()** in Python's builtins namespace, based on *domain* and *localedir* which are passed to the function **translation()**.

For the *names* parameter, please see the description of the translation object's **install()** method.

As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the **_()** function, like this:

```
print(_('This string will be translated.'))
```

For convenience, you want the **_()** function to be installed in Python's builtins namespace, so it is easily accessible in all modules of your application.

Changed in version 3.11: names is now a keyword-only parameter.

The NullTranslations class

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is **NullTranslations**; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of **NullTranslations**:

class gettext.NullTranslations(*fp=None*)

Takes an optional file object *fp*, which is ignored by the base class. Initializes "protected" instance variables *_info* and *_charset* which are set by derived classes, as well as *_fallback*, which is set through **`add_fallback()`**. It then calls `self._parse(fp)` if *fp* is not `None`.

_parse(*fp*)

No-op in the base class, this method takes file object *fp*, and reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

add_fallback(*fallback*)

Add *fallback* as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

gettext(*message*)

If a fallback has been set, forward **`gettext()`** to the fallback. Otherwise, return *message*. Overridden in derived classes.

ngettext(*singular*, *plural*, *n*)

If a fallback has been set, forward **`ngettext()`** to the fallback. Otherwise, return *singular* if *n* is 1; return *plural* otherwise. Overridden in derived classes.

pgettext(*context*, *message*)

If a fallback has been set, forward **`pgettext()`** to the fallback. Otherwise, return the translated message. Overridden in derived classes.

New in version 3.8.

npgettext(*context*, *singular*, *plural*, *n*)

If a fallback has been set, forward **npgettext()** to the fallback. Otherwise, return the translated message. Overridden in derived classes.

New in version 3.8.

info()

Return the "protected" **_info** variable, a dictionary containing the metadata found in the message catalog file.

charset()

Return the encoding of the message catalog file.

install(*names*=*None*)

This method installs **gettext()** into the built-in namespace, binding it to `_`.

If the *names* parameter is given, it must be a sequence containing the names of functions you want to install in the builtins namespace in addition to **_()**. Supported names are `'gettext'`, `'ngettext'`, `'pgettext'`, `'npgettext'`, `'lgettext'`, and `'lngettext'`.

Note that this is only one way, albeit the most convenient way, to make the **_()** function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install **_()**. Instead, they should use this code to make **_()** available to their module:

```
import gettext
t = gettext.translation('mymodule', ...)
_ = t.gettext
```

This puts **_()** only in the module's global namespace and so only affects calls within this module.

Changed in version 3.8: Added `'pgettext'` and `'npgettext'`.

The `GNUTranslations` class

The `gettext` module provides one additional class derived from `NullTranslations`: `GNUTranslations`. This class overrides `_parse()` to enable reading GNU **gettext** format `.mo` files in both big-endian and little-endian format.

`GNUTranslations` parses optional metadata out of the translation catalog. It is convention with GNU **gettext** to include metadata as the translation for the empty string. This metadata is in RFC 822 [https://datatracker.ietf.org/doc/html/rfc822.html]-style `key: value` pairs, and should contain the `Project-Id-Version` key. If the key `Content-Type` is found, then the `charset` property is used to initialize the "protected" `_charset` instance variable, defaulting to `None` if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding, else ASCII is assumed.

Since message ids are read as Unicode strings too, all `*gettext()` methods will assume message ids as Unicode strings, not byte strings.

The entire set of key/value pairs are placed into a dictionary and set as the "protected" `_info` instance variable.

If the `.mo` file's magic number is invalid, the major version number is unexpected, or if other problems occur while reading the file, instantiating a `GNUTranslations` class can raise `OSError`.

class gettext.GNUTranslations

The following methods are overridden from the base class implementation:

gettext(*message*)

Look up the *message* id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the *message* id, and a

fallback has been set, the look up is forwarded to the fallback's **gettext()** method. Otherwise, the *message* id is returned.

ngettext(*singular*, *plural*, *n*)

Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's **ngettext()** method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

Here is an example:

```
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
message = cat.ngettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory'
    n) % {'num': n}
```

pgettext(*context*, *message*)

Look up the *context* and *message* id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the *message* id and *context*, and a fallback has been set, the look up is forwarded to the fallback's **pgettext()** method. Otherwise, the *message* id is returned.

New in version 3.8.

npgettext(*context*, *singular*, *plural*, *n*)

Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form

to use.

If the message id for *context* is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's **`npgettext()`** method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

New in version 3.8.

Solaris message catalog support

The Solaris operating system defines its own binary `.mo` file format, but since no documentation can be found on this format, it is not supported at this time.

The Catalog constructor

GNOME uses a version of the **`gettext`** module by James Henstridge, but this version has a slightly different API. Its documented usage was:

```
import gettext
cat = gettext.Catalog(domain, localedir)
_ = cat.gettext
print(_('hello world'))
```

For compatibility with this older module, the function **`Catalog()`** is an alias for the **`translation()`** function described above.

One difference between this module and Henstridge's: his catalog objects supported access through a mapping API, but this appears to be unused and so is not currently supported.

Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N)

refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language-specific translations of the message catalogs
4. use the `gettext` module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in `_('...')` — that is, a call to the function `_()`. For example:

```
filename = 'mylog.txt'
message = _('writing a log message')
with open(filename, 'w') as fp:
    fp.write(message)
```

In this example, the string `'writing a log message'` is marked as a candidate for translation, while the strings `'mylog.txt'` and `'w'` are not.

There are a few tools to extract the strings meant for translation. The original GNU **gettext** only supported C or C++ source code but its extended version **xgettext** scans code written in a number of languages, including Python, to find strings marked as translatable. Babel [https://babel.pocoo.org/] is a Python internationalization library that includes a `pybabel` script to extract and compile message catalogs. François Pinard's program called **xpot** does a similar job and is available as part of his po-utils package [https://github.com/pinard/po-utils].

(Python also includes pure-Python versions of these programs, called **pygettext.py** and **msgfmt.py**; some Python distributions will install them for you. **pygettext.py** is similar to **xgettext**, but only understands Python source code and cannot handle other

programming languages such as C or C++. **pygettext.py** supports a command-line interface similar to **xgettext**; for details on its use, run `pygettext.py --help`. **msgfmt.py** is binary compatible with GNU **msgfmt**. With these two programs, you may not need the GNU **gettext** package to internationalize your Python applications.)

xgettext, **pygettext**, and similar tools generate `.po` files that are message catalogs. They are structured human-readable files that contain every marked string in the source code, along with a placeholder for the translated versions of these strings.

Copies of these `.po` files are then handed over to the individual human translators who write translations for every supported natural language. They send back the completed language-specific versions as a `<language-name>.po` file that's compiled into a machine-readable `.mo` binary catalog file using the **msgfmt** program. The `.mo` files are used by the **`gettext`** module for the actual translation processing at run-time.

How you use the **`gettext`** module in your code depends on whether you are internationalizing a single module or your entire application. The next two sections will discuss each case.

Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU **gettext** API but instead the class-based API.

Let's say your module is called "spam" and the module's various natural language translation `.mo` files reside in `/usr/share/locale` in GNU **gettext** format. Here's what you would put at the top of your module:

```
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.gettext
```

Localizing your application

If you are localizing your application, you can install the `_()` function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use `_('...')` without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```
import gettext
gettext.install('myapplication')
```

If you need to set the locale directory, you can pass it into the `install()` function:

```
import gettext
gettext.install('myapplication', '/usr/share/locale')
```

Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```
import gettext

lang1 = gettext.translation('myapplication', languages=[
lang2 = gettext.translation('myapplication', languages=[
lang3 = gettext.translation('myapplication', languages=[

# start by using language1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:

```
animals = ['mollusk',
           'albatross',
           'rat',
           'penguin',
           'python', ]
# ...
for a in animals:
    print(a)
```

Here, you want to mark the strings in the `animals` list as being translatable, but you don't actually want to translate them until they are printed.

Here is one way you can handle this situation:

```
def _(message): return message

animals = [_('mollusk'),
           _('albatross'),
           _('rat'),
           _('penguin'),
           _('python'), ]

del _

# ...
for a in animals:
    print(_(a))
```

This works because the dummy definition of **`_()`** simply returns the string unchanged. And this dummy definition will temporarily override any definition of **`_()`** in the built-in namespace (until the **`del`** command). Take care, though if you have a previous definition of **`_()`** in the local namespace.

Note that the second use of **`_()`** will not identify “a” as being translatable to the **gettext** program, because the parameter is not a string literal.

Another way to handle this is with the following example:

```
def N_(message): return message

animals = [N_('mollusk'),
           N_('albatross'),
           N_('rat'),
           N_('penguin'),
           N_('python'), ]

# ...
for a in animals:
    print(_(a))
```

In this case, you are marking translatable strings with the function **`N_()`**, which won’t conflict with any definition of **`_()`**. However, you will need to teach your message extraction program to look for translatable strings marked with **`N_()`**. **xgettext**, **pygettext**, `pybabel extract`, and **xpot** all support this through the use of the **`-k`** command-line switch. The choice of **`N_()`** here is totally arbitrary; it could have just as easily been **`MarkThisStringForTranslation()`**.

Footnotes

1

The default locale directory is system dependent; for example, on RedHat Linux it is `/usr/share/locale`, but on Solaris it is `/usr/lib/locale`. The **`gettext`** module does not try to support these system dependent defaults; instead its default is *`sys.base_prefix`*`/share/locale` (see **`sys.base_prefix`**). For this reason, it is always best to call **`bindtextdomain()`** with an explicit absolute path at the start of your application.

2

See the footnote for **`bindtextdomain()`** above.

`locale` — Internationalization services

Source code: Lib/locale.py [https://github.com/python/cpython/tree/3.11/Lib/locale.py]

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions:

exception locale.Error

Exception raised when the locale passed to `setlocale()` is not recognized.

locale.setlocale(*category*, *locale*=*None*)

If *locale* is given and not `None`, `setlocale()` modifies the locale setting for the *category*. The available categories are listed in the data description below. *locale* may be a string, or an iterable of two strings (language code and encoding). If it's an iterable, it's converted to a locale name using the locale aliasing engine. An empty string specifies the user's default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.

If *locale* is omitted or `None`, the current setting for *category* is

returned.

setlocale() is not thread-safe on most systems. Applications typically start with a call of

```
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user's default setting (typically specified in the **LANG** environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

locale.localeconv()

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

Category	Meaning
DECIMAL_POINT	Decimal point character.
GROUPING	Sequence of numbers specifying which relative positions the `'thousands_sep'` is expected. If the sequence is terminated with **CHAR_MAX**, no further grouping is performed. If the sequence terminates with a `0`, the last group size is repeatedly used.
THOUSANDS_SEP	Character used between groups.
INT_CURR_SYMBOL	International currency symbol.
CURRENCY_SYMBOL	Local currency symbol.
P_CS_PRECEDES, **N_CS_PRECEDES**	Whether the currency symbol precedes the value (for positive resp. negative values).
P_SEP_BY_SPACE, **N_SEP_BY_SPACE**	Whether the currency symbol is separated from the value by a space (for positive resp. negative values).
MON_DECIMAL_POINT	Decimal point used for monetary values.
FRAC_DIGITS	Number of fractional digits used in local formatting of monetary values.
INT_FRAC_DIGITS	Number of fractional digits used in international formatting of monetary values.
MON_THOUSANDS_SEP	Group separator used for monetary values.
MON_GROUPING	Equivalent to `'grouping'`, used for monetary values.
POSITIVE_SIGN	Symbol used to annotate a positive monetary value.
NEGATIVE_SIGN	Symbol used to annotate a negative monetary value.

p_sep_by_space, n_sep_by_space

The position of the sign (for positive resp. negative values), see below.

All numeric values can be set to **CHAR_MAX** to indicate that there is no value specified in this locale.

The possible values for `'p_sign_posn'` and `'n_sign_posn'` are given below.

Value	Explanation
0	Currency and value are surrounded by parentheses.
1	The sign should precede the value and currency symbol.
2	The sign should follow the value and currency symbol.
3	The sign should immediately precede the value.
4	The sign should immediately follow the value.
CHAR_MAX	Nothing is specified in this locale.

The function temporarily sets the `LC_CTYPE` locale to the `LC_NUMERIC` locale or the `LC_MONETARY` locale if locales are different and numeric or monetary strings are non-ASCII. This temporary change affects other threads.

Changed in version 3.7: The function now temporarily sets the `LC_CTYPE` locale to the `LC_NUMERIC` locale in some cases.

locale.nl_langinfo(*option*)

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are numbers, for which symbolic constants are available in the locale module.

The **nl_langinfo()** function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

locale.CODESET

Get a string with the name of the character encoding used in the selected locale.

locale.D_T_FMT

Get a string that can be used as a format string for `time.strftime()` to represent date and time in a locale-specific way.

locale.D_FMT

Get a string that can be used as a format string for `time.strftime()` to represent a date in a locale-specific way.

locale.T_FMT

Get a string that can be used as a format string for `time.strftime()` to represent a time in a locale-specific way.

locale.T_FMT_AMPM

Get a format string for `time.strftime()` to represent time in the am/pm format.

DAY_1 ... DAY_7

Get the name of the n-th day of the week.

Note

This follows the US convention of `DAY_1` being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

ABDAY_1 ... ABDAY_7

Get the abbreviated name of the n-th day of the week.

MON_1 ... MON_12

Get the name of the n-th month.

ABMON_1 ... ABMON_12

Get the abbreviated name of the n-th month.

locale.RADIXCHAR

Get the radix character (decimal dot, decimal comma, etc.).

locale.THOUSEP

Get the separator character for thousands (groups of three digits).

locale.YESEXPR

Get a regular expression that can be used with the regex function to recognize a positive response to a yes/no question.

locale.NOEXPR

Get a regular expression that can be used with the regex(3) function to recognize a negative response to a yes/no question.

Note

The regular expressions for **YESEXPR** and **NOEXPR** use syntax suitable for the **regex()** function from the C library, which might differ from the syntax used in **re**.

locale.CRNCYSTR

Get the currency symbol, preceded by "-" if the symbol should appear before the value, "+" if the symbol should appear after the value, or "." if the symbol should replace the radix character.

locale.ERA

Get a string that represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one.

In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor's reign.

Normally it should not be necessary to use this value directly. Specifying the `E` modifier in their format strings causes the **`time.strftime()`** function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

locale.ERA_D_T_FMT

Get a format string for **`time.strftime()`** to represent date and time in a locale-specific era-based way.

locale.ERA_D_FMT

Get a format string for **`time.strftime()`** to represent a date in a locale-specific era-based way.

locale.ERA_T_FMT

Get a format string for **`time.strftime()`** to represent a time in a locale-specific era-based way.

locale.ALT_DIGITS

Get a representation of up to 100 values used to represent the values 0 to 99.

locale.getdefaultlocale([*envvars*])

Tries to determine the default locale settings and returns them as a tuple of the form `(language code, encoding)`.

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable `'C'` locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the **`LANG`** variable. Since we do not want to interfere with the current locale setting we thus

emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the **LANG** variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. *envvars* defaults to the search path used in GNU gettext; it must always contain the variable name `'LANG'`. The GNU gettext search path contains `'LC_ALL'`, `'LC_CTYPE'`, `'LANG'` and `'LANGUAGE'`, in that order.

Except for the code `'C'`, the language code corresponds to **RFC 1766** [https://datatracker.ietf.org/doc/html/rfc1766.html]. *language code* and *encoding* may be `None` if their values cannot be determined.

Deprecated since version 3.11, will be removed in version 3.13.

locale.getlocale(*category=LC_CTYPE*)

Returns the current setting for the given locale category as sequence containing *language code*, *encoding*. *category* may be one of the **LC_*** values except **LC_ALL**. It defaults to **LC_CTYPE**.

Except for the code `'C'`, the language code corresponds to **RFC 1766** [https://datatracker.ietf.org/doc/html/rfc1766.html]. *language code* and *encoding* may be `None` if their values cannot be determined.

locale.getpreferredencoding(*do_setlocale=True*)

Return the locale encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke **setlocale()** to obtain the user preferences, so this function is not thread-safe. If invoking setlocale is not necessary or desired, *do_setlocale* should be set to `False`.

On Android or if the Python UTF-8 Mode is enabled, always return `'utf-8'`, the locale encoding and the *do_setlocale* argument are ignored.

The Python preinitialization configures the LC_CTYPE locale. See also the filesystem encoding and error handler.

Changed in version 3.7: The function now always returns `"utf-8"` on Android or if the Python UTF-8 Mode is enabled.

locale.getencoding()

Get the current locale encoding:

- On Android and VxWorks, return `"utf-8"`.
- On Unix, return the encoding of the current **`LC_CTYPE`** locale. Return `"utf-8"` if `nl_langinfo(CODESET)` returns an empty string: for example, if the current LC_CTYPE locale is not supported.
- On Windows, return the ANSI code page.

The Python preinitialization configures the LC_CTYPE locale. See also the filesystem encoding and error handler.

This function is similar to **`getpreferredencoding(False)`** except this function ignores the Python UTF-8 Mode.

New in version 3.11.

locale.normalize(*localename*)

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with **`setlocale()`**. If normalization fails, the original name is returned unchanged.

If the given encoding is not known, the function defaults to the default encoding for the locale code just like **`setlocale()`**.

locale.resetlocale(*category=LC_ALL*)

Sets the locale for *category* to the default setting.

The default setting is determined by calling **`getdefaultlocale()`**. *category* defaults to **`LC_ALL`**.

Deprecated since version 3.11, will be removed in version 3.13.

locale.strcoll(*string1*, *string2*)

Compares two strings according to the current **`LC_COLLATE`** setting. As any other compare function, returns a negative, or a positive value, or `0`, depending on whether *string1* collates before or after *string2* or is equal to it.

locale.strxfrm(*string*)

Transforms a string to one that can be used in locale-aware comparisons. For example, `strxfrm(s1) < strxfrm(s2)` is equivalent to `strcoll(s1, s2) < 0`. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

locale.format_string(*format*, *val*, *grouping*=*False*, *monetary*=*False*)

Formats a number *val* according to the current **`LC_NUMERIC`** setting. The format follows the conventions of the `%` operator. For floating point values, the decimal point is modified if appropriate. If *grouping* is `True`, also takes the grouping into account.

If *monetary* is true, the conversion uses monetary thousands separator and grouping strings.

Processes formatting specifiers as in `format % val`, but takes the current locale settings into account.

Changed in version 3.7: The *monetary* keyword parameter was added.

locale.format(*format*, *val*, *grouping*=*False*, *monetary*=*False*)

Please note that this function works like **`format_string()`** but will only work for exactly one `%char` specifier. For

example, `'%f'` and `'%.0f'` are both valid specifiers, but `'%f KiB'` is not.

For whole format strings, use **`format_string()`**.

Deprecated since version 3.7: Use **`format_string()`** instead.

locale.currency(*val*, *symbol*=*True*, *grouping*=*False*, *international*=*False*)

Formats a number *val* according to the current **`LC_MONETARY`** settings.

The returned string includes the currency symbol if *symbol* is true, which is the default. If *grouping* is `True` (which is not the default), grouping is done with the value. If *international* is `True` (which is not the default), the international currency symbol is used.

Note

This function will not work with the 'C' locale, so you have to set a locale via **`setlocale()`** first.

locale.str(*float*)

Formats a floating point number using the same format as the built-in function `str(float)`, but takes the decimal point into account.

locale.delocalize(*string*)

Converts a string into a normalized number string, following the **`LC_NUMERIC`** settings.

New in version 3.5.

locale.localize(*string*, *grouping*=*False*, *monetary*=*False*)

Converts a normalized number string into a formatted string following the **`LC_NUMERIC`** settings.

New in version 3.10.

locale.atof(*string*, *func*=*float*)

Converts a string to a number, following the **LC_NUMERIC** settings, by calling *func* on the result of calling **delocalize()** on *string*.

locale.atoi(*string*)

Converts a string to an integer, following the **LC_NUMERIC** conventions.

locale.LC_CTYPE

Locale category for the character type functions. Depending on the settings of this category, the functions of module **string** dealing with case change their behaviour.

locale.LC_COLLATE

Locale category for sorting strings. The functions **strcoll()** and **strxfrm()** of the **locale** module are affected.

locale.LC_TIME

Locale category for the formatting of time. The function **time.strftime()** follows these conventions.

locale.LC_MONETARY

Locale category for formatting of monetary values. The available options are available from the **localeconv()** function.

locale.LC_MESSAGES

Locale category for message display. Python currently does not support application specific locale-aware messages. Messages displayed by the operating system, like those returned by **os.strerror()** might be affected by this category.

locale.LC_NUMERIC

Locale category for formatting numbers. The functions **format()**, **atoi()**, **atof()** and **str()** of the **locale** module are affected by that category. All other numeric formatting operations are not affected.

locale.LC_ALL

Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

locale.CHAR_MAX

This is a symbolic constant used for different values returned by **localeconv()**.

Example:

```
>>> import locale
>>> loc = locale.getlocale()  # get current locale
# use German locale; name might vary with platform
>>> locale.setlocale(locale.LC_ALL, 'de_DE')
>>> locale.strcoll('f\xe4n', 'foo')  # compare a string
>>> locale.setlocale(locale.LC_ALL, '')   # use user's p
>>> locale.setlocale(locale.LC_ALL, 'C')  # use default
>>> locale.setlocale(locale.LC_ALL, loc)  # restore save
```

Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementations are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the `C` locale, no matter what the user's preferred locale is. There is one exception: the **`LC_CTYPE`** category is changed at startup to set the current locale encoding to the user's preferred locale encoding. The program must explicitly say that it wants the user's preferred locale settings for other categories by calling `setlocale(LC_ALL, '')`.

It is generally a bad idea to call **`setlocale()`** in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as certain formats used with **`time.strftime()`**), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-`C` locale settings.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: **`atof()`**, **`atoi()`**, **`format()`**, **`str()`**.

There is no way to perform case conversions and character classifications according to the locale. For (Unicode) text strings these are done according to the character value only, while for byte strings, the conversions and classifications are done according to the ASCII value of the byte, and bytes whose high bit is set (i.e., non-ASCII bytes) are never converted or considered part of a character class such as letter or whitespace.

For extension writers and programs that embed Python

Extension modules should never call **`setlocale()`**, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is `C`).

When Python code uses the **locale** module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the **_locale** extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the **_locale** module is not accessible as a shared library.

Access to message catalogs

locale.gettext(*msg*)

locale.dgettext(*domain*, *msg*)

locale.dcgettext(*domain*, *msg*, *category*)

locale.textdomain(*domain*)

locale.bindtextdomain(*domain*, *dir*)

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions **gettext()**, **dgettext()**, **dcgettext()**, **textdomain()**, **bindtextdomain()**, and **bind_textdomain_codeset()**. These are similar to the same functions in the **gettext** module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use **gettext** instead. A known exception to this rule are applications that link with additional C libraries which internally invoke **gettext()** or **dcgettext()**. For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.

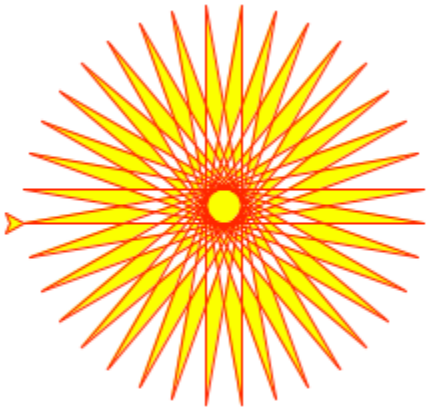
Program Frameworks

The modules described in this chapter are frameworks that will largely dictate the structure of your program. Currently the modules described here are all oriented toward writing command-line interfaces.

The full list of modules described in this chapter is:

- `turtle` — Turtle graphics
  - Introduction
  - Overview of available Turtle and Screen methods
    - Turtle methods
    - Methods of TurtleScreen/Screen
  - Methods of RawTurtle/Turtle and corresponding functions
    - Turtle motion
    - Tell Turtle's state
    - Settings for measurement
    - Pen control
      - Drawing state
      - Color control
      - Filling
      - More drawing control
    - Turtle state
      - Visibility
      - Appearance
    - Using events
    - Special Turtle methods
    - Compound shapes

    - Methods of TurtleScreen/Screen and corresponding functions
        - Window control
        - Animation control
        - Using screen events
        - Input methods
        - Settings and special methods
        - Methods specific to Screen, not inherited from TurtleScreen
    - Public classes
    - Help and configuration
        - How to use help
        - Translation of docstrings into different languages
        - How to configure Screen and Turtles
    - **turtledemo** — Demo scripts
    - Changes since Python 2.6
    - Changes since Python 3.0
- **cmd** — Support for line-oriented command interpreters
    - Cmd Objects
    - Cmd Example
- **shlex** — Simple lexical analysis
    - shlex Objects
    - Parsing Rules
    - Improved Compatibility with Shells



`turtle` — Turtle graphics

Source code: Lib/turtle.py [https://github.com/python/cpython/tree/3.11/Lib/turtle.py]

Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzeig, Seymour Papert and Cynthia Solomon in 1967.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. After an `import turtle`, give it the command `turtle.forward(15)`, and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command `turtle.right(25)`, and it rotates in-place 25 degrees clockwise.

Turtle star

Turtle can draw intricate shapes using programs that repeat simple moves.

```
from turtle import *
color('red', 'yellow')
begin_fill()
while True:
    forward(200)
    left(170)
    if abs(pos()) < 1:
        break
end_fill()
done()
```

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The **`turtle`** module is an extended reimplementation of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the `-n` switch.

The turtle module provides turtle graphics primitives, in both object-oriented and procedure-oriented ways. Because it uses **`tkinter`** for the underlying graphics, it needs a version of Python installed with Tk support.

The object-oriented interface uses essentially two + two classes:

1. The **`TurtleScreen`** class defines graphics windows as a playground for the drawing turtles. Its constructor needs a **`tkinter.Canvas`** or a **`ScrolledCanvas`** as argument. It should be used when **`turtle`** is used as part of some application.

   The function **`Screen()`** returns a singleton object of a **`TurtleScreen`** subclass. This function should be used when **`turtle`** is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

All methods of TurtleScreen/Screen also exist as functions, i.e. as part of the procedure-oriented interface.

2. **`RawTurtle`** (alias: **`RawPen`**) defines Turtle objects which draw on a **`TurtleScreen`**. Its constructor needs a Canvas, ScrolledCanvas or TurtleScreen as argument, so the RawTurtle objects know where to draw.

   Derived from RawTurtle is the subclass **`Turtle`** (alias: **`Pen`**), which draws on "the" **`Screen`** instance which is automatically created, if not already present.

   All methods of RawTurtle/Turtle also exist as functions, i.e. part of the procedure-oriented interface.

The procedural interface provides functions which are derived from the methods of the classes **`Screen`** and **`Turtle`**. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a Screen method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles on a screen one has to use the object-oriented interface.

Note

In the following documentation the argument list for functions is given. Methods, of course, have the additional first argument *self* which is omitted here.

Overview of available Turtle and Screen methods

Turtle methods

Turtle motion

Move and draw

```
forward() | fd()
backward() | bk() | back()
right() | rt()
left() | lt()
goto() | setpos() | setposition()
setx()
sety()
setheading() | seth()
home()
circle()
dot()
stamp()
clearstamp()
clearstamps()
undo()
speed()
```

Tell Turtle's state

```
position() | pos()
towards()
xcor()
ycor()
heading()
distance()
```

Setting and measurement

```
degrees()
radians()
```

Pen control

Drawing state

```
pendown() | pd() | down()
penup() | pu() | up()
pensize() | width()
pen()
```

`isdown()`

Color control

`color()`
`pencolor()`
`fillcolor()`

Filling

`filling()`
`begin_fill()`
`end_fill()`

More drawing control

`reset()`
`clear()`
`write()`

Turtle state

Visibility

`showturtle()` | `st()`
`hideturtle()` | `ht()`
`isvisible()`

Appearance

`shape()`
`resizemode()`
`shapesize()` | `turtlesize()`
`shearfactor()`
`settiltangle()`
`tiltangle()`
`tilt()`
`shapetransform()`
`get_shapepoly()`

Using events

```
onclick()
onrelease()
ondrag()
```

Special Turtle methods

```
begin_poly()
end_poly()
get_poly()
clone()
getturtle() | getpen()
getscreen()
setundobuffer()
undobufferentries()
```

Methods of TurtleScreen/Screen

Window control

```
bgcolor()
bgpic()
clearscreen()
resetscreen()
screensize()
setworldcoordinates()
```

Animation control

```
delay()
tracer()
update()
```

Using screen events

```
listen()
onkey() | onkeyrelease()
onkeypress()
onclick() | onscreenclick()
ontimer()
mainloop() | done()
```

Settings and special methods

mode()
colormode()
getcanvas()
getshapes()
register_shape() | **addshape()**
turtles()
window_height()
window_width()

Input methods

textinput()
numinput()

Methods specific to Screen

bye()
exitonclick()
setup()
title()

Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called `turtle`.

Turtle motion

turtle.forward(*distance*)
turtle.fd(*distance*)

Parameters

distance – a number (integer or float)

Move the turtle forward by the specified *distance*, in the direction the turtle is headed.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00,0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00,0.00)
```

turtle.back(*distance*)
turtle.bk(*distance*)
turtle.backward(*distance*)

Parameters

distance – a number

Move the turtle backward by *distance*, opposite to the direction the turtle is headed. Do not change the turtle's heading.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.backward(30)
>>> turtle.position()
(-30.00,0.00)
```

turtle.right(*angle*)
turtle.rt(*angle*)

Parameters

angle – a number (integer or float)

Turn turtle right by *angle* units. (Units are by default degrees, but can be set via the **degrees()** and **radians()** functions.) Angle orientation depends on the turtle mode, see **mode()**.

```
>>> turtle.heading()
```

```
22.0
>>> turtle.right(45)
>>> turtle.heading()
337.0
```

turtle.left(*angle*)
turtle.lt(*angle*)

Parameters

angle – a number (integer or float)

Turn turtle left by *angle* units. (Units are by default degrees, but can be set via the **degrees()** and **radians()** functions.) Angle orientation depends on the turtle mode, see **mode()**.

```
>>> turtle.heading()
22.0
>>> turtle.left(45)
>>> turtle.heading()
67.0
```

turtle.goto(*x*, *y*=*None*)
turtle.setpos(*x*, *y*=*None*)
turtle.setposition(*x*, *y*=*None*)

Parameters

- **x** – a number or a pair/vector of numbers
- **y** – a number or `None`

If *y* is `None`, *x* must be a pair of coordinates or a **Vec2D** (e.g. as returned by **pos()**).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```
>>> tp = turtle.pos()
>>> tp
```

```
(0.00,0.00)
>>> turtle.setpos(60,30)
>>> turtle.pos()
(60.00,30.00)
>>> turtle.setpos((20,80))
>>> turtle.pos()
(20.00,80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00,0.00)
```

turtle.setx(*x*)

Parameters

x – a number (integer or float)

Set the turtle's first coordinate to *x*, leave second coordinate unchanged.

```
>>> turtle.position()
(0.00,240.00)
>>> turtle.setx(10)
>>> turtle.position()
(10.00,240.00)
```

turtle.sety(*y*)

Parameters

y – a number (integer or float)

Set the turtle's second coordinate to *y*, leave first coordinate unchanged.

```
>>> turtle.position()
(0.00,40.00)
>>> turtle.sety(-10)
>>> turtle.position()
(0.00,-10.00)
```

turtle.setheading(*to_angle*)
turtle.seth(*to_angle*)

Parameters

to_angle – a number (integer or float)

Set the orientation of the turtle to *to_angle*. Here are some common directions in degrees:

standard mode	logo mode
0 - east	0 - north
90 - north	90 - east
180 - west	180 - south
270 - south	270 - west

```
>>> turtle.setheading(90)
>>> turtle.heading()
90.0
```

turtle.home()

Move turtle to the origin – coordinates (0,0) – and set its heading to its start-orientation (which depends on the mode, see `mode()`).

```
>>> turtle.heading()
90.0
>>> turtle.position()
(0.00,-10.00)
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.circle(*radius*, *extent*=*None*, *steps*=*None*)

Parameters

- **radius** – a number
- **extent** – a number (or `None`)

- **steps** – an integer (or `None`)

Draw a circle with given *radius*. The center is *radius* units left of the turtle; *extent* – an angle – determines which part of the circle is drawn. If *extent* is not given, draw the entire circle. If *extent* is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if *radius* is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of *extent*.

As the circle is approximated by an inscribed regular polygon, *steps* determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(50)
>>> turtle.position()
(-0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(120, 180)  # draw a semicircle
>>> turtle.position()
(0.00,240.00)
>>> turtle.heading()
180.0
```

turtle.dot(*size=None*, **color*)

Parameters

- **size** – an integer >= 1 (if given)
- **color** – a colorstring or a numeric color tuple

Draw a circular dot with diameter *size*, using *color*. If *size* is not given, the maximum of pensize + 4 and 2*pensize is used.

```
>>> turtle.home()
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle.f
>>> turtle.position()
(100.00,-0.00)
>>> turtle.heading()
0.0
```

turtle.stamp()

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a stamp_id for that stamp, which can be used to delete it by calling `clearstamp(stamp_id)`.

```
>>> turtle.color("blue")
>>> turtle.stamp()
11
>>> turtle.fd(50)
```

turtle.clearstamp(*stampid*)

Parameters

stampid – an integer, must be return value of previous **`stamp()`** call

Delete stamp with given *stampid*.

```
>>> turtle.position()
(150.00,-0.00)
>>> turtle.color("blue")
>>> astamp = turtle.stamp()
>>> turtle.fd(50)
>>> turtle.position()
(200.00,-0.00)
>>> turtle.clearstamp(astamp)
>>> turtle.position()
```

```
(200.00,-0.00)
```

turtle.clearstamps(*n*=*None*)

Parameters

n – an integer (or `None`)

Delete all or first/last *n* of turtle's stamps. If *n* is `None`, delete all stamps, if $n > 0$ delete first *n* stamps, else if $n < 0$ delete last *n* stamps.

```
>>> for i in range(8):
...     turtle.stamp(); turtle.fd(30)
13
14
15
16
17
18
19
20
>>> turtle.clearstamps(2)
>>> turtle.clearstamps(-2)
>>> turtle.clearstamps()
```

turtle.undo()

Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

```
>>> for i in range(4):
...     turtle.fd(50); turtle.lt(80)
...
>>> for i in range(8):
...     turtle.undo()
```

turtle.speed(*speed*=*None*)

Parameters

speed – an integer in the range 0..10 or a speedstring (see below)

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows:

- "fastest": 0
- "fast": 10
- "normal": 6
- "slow": 3
- "slowest": 1

Speeds from 1 to 10 enforce increasingly faster animation of line drawing and turtle turning.

Attention: *speed* = 0 means that *no* animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

```
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
```

Tell Turtle's state

turtle.position()
turtle.pos()

Return the turtle's current location (x,y) (as a **Vec2D** vector).

```
>>> turtle.pos()
```

```
(440.00,-0.00)
```

turtle.towards(*x*, *y*=*None*)

Parameters

- **x** – a number or a pair/vector of numbers or a turtle instance
- **y** – a number if *x* is a number, else `None`

Return the angle between the line from turtle position to position specified by (x,y), the vector or the other turtle. This depends on the turtle's start orientation which depends on the mode - "standard"/"world" or "logo".

```
>>> turtle.goto(10, 10)
>>> turtle.towards(0,0)
225.0
```

turtle.xcor()

Return the turtle's x coordinate.

```
>>> turtle.home()
>>> turtle.left(50)
>>> turtle.forward(100)
>>> turtle.pos()
(64.28,76.60)
>>> print(round(turtle.xcor(), 5))
64.27876
```

turtle.ycor()

Return the turtle's y coordinate.

```
>>> turtle.home()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print(turtle.pos())
(50.00,86.60)
```

```
>>> print(round(turtle.ycor(), 5))
86.60254
```

turtle.heading()

Return the turtle's current heading (value depends on the turtle mode, see **`mode()`**).

```
>>> turtle.home()
>>> turtle.left(67)
>>> turtle.heading()
67.0
```

turtle.distance(*x*, *y=None*)

Parameters

- **x** – a number or a pair/vector of numbers or a turtle instance
- **y** – a number if *x* is a number, else `None`

Return the distance from the turtle to (x,y), the given vector, or the given other turtle, in turtle step units.

```
>>> turtle.home()
>>> turtle.distance(30,40)
50.0
>>> turtle.distance((30,40))
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

Settings for measurement

turtle.degrees(*fullcircle=360.0*)

Parameters

fullcircle – a number

Set angle measurement units, i.e. set number of “degrees” for a full circle. Default value is 360 degrees.

```
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0

Change angle measurement unit to grad (also known a
grade, or gradian and equals 1/100-th of the right
>>> turtle.degrees(400.0)
>>> turtle.heading()
100.0
>>> turtle.degrees(360)
>>> turtle.heading()
90.0
```

turtle.radians()

Set the angle measurement units to radians. Equivalent to `degrees(2*math.pi)`.

```
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
>>> turtle.radians()
>>> turtle.heading()
1.5707963267948966
```

Pen control

Drawing state

turtle.pendown()
turtle.pd()
turtle.down()

Pull the pen down – drawing when moving.

turtle.penup()
turtle.pu()
turtle.up()

Pull the pen up – no drawing when moving.

turtle.pensize(*width=None*)
turtle.width(*width=None*)

Parameters

width – a positive number

Set the line thickness to *width* or return it. If resizemode is set to "auto" and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```
>>> turtle.pensize()
1
>>> turtle.pensize(10)   # from here on lines of wi
```

turtle.pen(*pen=None*, ***pendict*)

Parameters

- **pen** – a dictionary with some or all of the below listed keys
- **pendict** – one or more keyword-arguments with the below listed keys as keywords

Return or set the pen's attributes in a "pen-dictionary" with the following key/value pairs:

- "shown": True/False
- "pendown": True/False
- "pencolor": color-string or color-tuple
- "fillcolor": color-string or color-tuple

- “pensize”: positive number
- “speed”: number in range 0..10
- “resizemode”: “auto” or “user” or “noresize”
- “stretchfactor”: (positive number, positive number)
- “outline”: positive number
- “tilt”: number

This dictionary can be used as argument for a subsequent call to **`pen()`** to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```
>>> turtle.pen(fillcolor="black", pencolor="red", p
>>> sorted(turtle.pen().items())
[('fillcolor', 'black'), ('outline', 1), ('pencolor
 ('pendown', True), ('pensize', 10), ('resizemode',
 ('shearfactor', 0.0), ('shown', True), ('speed', 9
 ('stretchfactor', (1.0, 1.0)), ('tilt', 0.0)]
>>> penstate=turtle.pen()
>>> turtle.color("yellow", "")
>>> turtle.penup()
>>> sorted(turtle.pen().items())[:3]
[('fillcolor', ''), ('outline', 1), ('pencolor', 'y
>>> turtle.pen(penstate, fillcolor="green")
>>> sorted(turtle.pen().items())[:3]
[('fillcolor', 'green'), ('outline', 1), ('pencolor
```

turtle.isdown()

Return `True` if pen is down, `False` if it’s up.

```
>>> turtle.penup()
>>> turtle.isdown()
False
>>> turtle.pendown()
>>> turtle.isdown()
True
```

Color control

turtle.pencolor(**args*)

Return or set the pencolor.

Four input formats are allowed:

`pencolor()`
: Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

`pencolor(colorstring)`
: Set pencolor to *colorstring*, which is a Tk color specification string, such as `"red"`, `"yellow"`, or `"#33cc8c"`.

`pencolor((r, g, b))`
: Set pencolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see **`colormode()`**).

`pencolor(r, g, b)`
: Set pencolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```
>>> colormode()
1.0
>>> turtle.pencolor()
'red'
>>> turtle.pencolor("brown")
>>> turtle.pencolor()
'brown'
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>> colormode(255)
```

```
>>> turtle.pencolor()
(51.0, 204.0, 140.0)
>>> turtle.pencolor('#32c18f')
>>> turtle.pencolor()
(50.0, 193.0, 143.0)
```

turtle.fillcolor(**args*)

Return or set the fillcolor.

Four input formats are allowed:

`fillcolor()`
: Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

`fillcolor(colorstring)`
: Set fillcolor to *colorstring*, which is a Tk color specification string, such as `"red"`, `"yellow"`, or `"#33cc8c"`.

`fillcolor((r, g, b))`
: Set fillcolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see **`colormode()`**).

`fillcolor(r, g, b)`
: Set fillcolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.

```
>>> turtle.fillcolor("violet")
>>> turtle.fillcolor()
'violet'
>>> turtle.pencolor()
(50.0, 193.0, 143.0)
>>> turtle.fillcolor((50, 193, 143))  # Integers,
```

```
>>> turtle.fillcolor()
(50.0, 193.0, 143.0)
>>> turtle.fillcolor('#ffffff')
>>> turtle.fillcolor()
(255.0, 255.0, 255.0)
```

turtle.color(**args*)

Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:

`color()`
: Return the current pencolor and the current fillcolor as a pair of color specification strings or tuples as returned by **`pencolor()`** and **`fillcolor()`**.

`color(colorstring), color((r,g,b)), color(r,g,b)`
: Inputs as in **`pencolor()`**, set both, fillcolor and pencolor, to the given value.

`color(colorstring1, colorstring2), color((r1,g1,b1), (r2,g2,b2))`
: Equivalent to `pencolor(colorstring1)` and `fillcolor(colorstring2)` and analogously if the other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is drawn with the newly set colors.

```
>>> turtle.color("red", "green")
>>> turtle.color()
('red', 'green')
>>> color("#285078", "#a0c8f0")
>>> color()
((40.0, 80.0, 120.0), (160.0, 200.0, 240.0))
```

See also: Screen method **`colormode()`**.

Filling

turtle.filling()

Return fillstate (`True` if filling, `False` else).

```
>>> turtle.begin_fill()
>>> if turtle.filling():
...     turtle.pensize(5)
... else:
...     turtle.pensize(3)
```

turtle.begin_fill()

To be called just before drawing a shape to be filled.

turtle.end_fill()

Fill the shape drawn after the last call to **`begin_fill()`**.

Whether or not overlap regions for self-intersecting polygons or multiple shapes are filled depends on the operating system graphics, type of overlap, and number of overlaps. For example, the Turtle star above may be either all yellow or have some white regions.

```
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

More drawing control

turtle.reset()

Delete the turtle's drawings from the screen, re-center the turtle and set variables to the default values.

```
>>> turtle.goto(0,-22)
>>> turtle.left(100)
>>> turtle.position()
(0.00,-22.00)
```

```
>>> turtle.heading()
100.0
>>> turtle.reset()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.clear()

Delete the turtle's drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.write(*arg*, *move=False*, *align='left'*, *font=('Arial', 8, 'normal')*)

Parameters

- **arg** – object to be written to the TurtleScreen
- **move** – True/False
- **align** – one of the strings "left", "center" or right"
- **font** – a triple (fontname, fontsize, fonttype)

Write text - the string representation of *arg* - at the current turtle position according to *align* ("left", "center" or "right") and with the given font. If *move* is true, the pen is moved to the bottom-right corner of the text. By default, *move* is `False`.

```
>>> turtle.write("Home = ", True, align="center")
>>> turtle.write((0,0), True)
```

Turtle state

Visibility

turtle.hideturtle()

turtle.ht()

Make the turtle invisible. It's a good idea to do this while you're in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

```
>>> turtle.hideturtle()
```

turtle.showturtle()

turtle.st()

Make the turtle visible.

```
>>> turtle.showturtle()
```

turtle.isvisible()

Return `True` if the Turtle is shown, `False` if it's hidden.

```
>>> turtle.hideturtle()
>>> turtle.isvisible()
False
>>> turtle.showturtle()
>>> turtle.isvisible()
True
```

Appearance

turtle.shape(*name*=*None*)

Parameters

name – a string which is a valid shapename

Set turtle shape to shape with given *name* or, if name is not given, return name of current shape. Shape with *name* must exist in the TurtleScreen's shape dictionary. Initially there are the following polygon shapes: "arrow", "turtle", "circle", "square", "triangle", "classic". To learn about how to deal with shapes see Screen method **`register_shape()`**.

```
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

turtle.resizemode(*rmode=None*)

Parameters

rmode – one of the strings “auto”, “user”, “noresize”

Set resizemode to one of the values: “auto”, “user”, “noresize”. If *rmode* is not given, return current resizemode. Different resizemodes have the following effects:

- “auto”: adapts the appearance of the turtle corresponding to the value of pensize.
- “user”: adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by `shapesize()`.
- “noresize”: no adaption of the turtle’s appearance takes place.

`resizemode("user")` is called by `shapesize()` when used with arguments.

```
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
>>> turtle.resizemode()
'auto'
```

turtle.shapesize(*stretch_wid=None*, *stretch_len=None*, *outline=None*)
turtle.turtlesize(*stretch_wid=None*, *stretch_len=None*, *outline=None*)

Parameters

- **stretch_wid** – positive number
- **stretch_len** – positive number

- **outline** – positive number

Return or set the pen's attributes x/y-stretchfactors and/or outline. Set resizemode to "user". If and only if resizemode is set to "user", the turtle will be displayed stretched according to its stretchfactors: *stretch_wid* is stretchfactor perpendicular to its orientation, *stretch_len* is stretchfactor in direction of its orientation, *outline* determines the width of the shapes's outline.

```
>>> turtle.shapesize()
(1.0, 1.0, 1)
>>> turtle.resizemode("user")
>>> turtle.shapesize(5, 5, 12)
>>> turtle.shapesize()
(5, 5, 12)
>>> turtle.shapesize(outline=8)
>>> turtle.shapesize()
(5, 5, 8)
```

turtle.shearfactor(*shear=None*)

Parameters

shear – number (optional)

Set or return the current shearfactor. Shear the turtleshape according to the given shearfactor shear, which is the tangent of the shear angle. Do *not* change the turtle's heading (direction of movement). If shear is not given: return the current shearfactor, i. e. the tangent of the shear angle, by which lines parallel to the heading of the turtle are sheared.

```
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.shearfactor(0.5)
>>> turtle.shearfactor()
0.5
```

turtle.tilt(*angle*)

Parameters

angle – a number

Rotate the turtleshape by *angle* from its current tilt-angle, but do *not* change the turtle's heading (direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

turtle.settiltangle(*angle*)

Parameters

angle – a number

Rotate the turtleshape to point in the direction specified by *angle*, regardless of its current tilt-angle. *Do not* change the turtle's heading (direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.settiltangle(45)
>>> turtle.fd(50)
>>> turtle.settiltangle(-45)
>>> turtle.fd(50)
```

Deprecated since version 3.1.

turtle.tiltangle(*angle=None*)

Parameters

angle – a number (optional)

Set or return the current tilt-angle. If angle is given, rotate the

turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. Do *not* change the turtle's heading (direction of movement). If angle is not given: return the current tilt-angle, i. e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()
45.0
```

turtle.shapetransform(*t11=None*, *t12=None*, *t21=None*, *t22=None*)

Parameters

- **t11** – a number (optional)
- **t12** – a number (optional)
- **t21** – a number (optional)
- **t12** – a number (optional)

Set or return the current transformation matrix of the turtle shape.

If none of the matrix elements are given, return the transformation matrix as a tuple of 4 elements. Otherwise set the given elements and transform the turtleshape according to the matrix consisting of first row t11, t12 and second row t21, t22. The determinant t11 * t22 - t12 * t21 must not be zero, otherwise an error is raised. Modify stretchfactor, shearfactor and tiltangle according to the given matrix.

```
>>> turtle = Turtle()
>>> turtle.shape("square")
>>> turtle.shapesize(4,2)
>>> turtle.shearfactor(-0.5)
>>> turtle.shapetransform()
```

```
(4.0, -1.0, -0.0, 2.0)
```

turtle.get_shapepoly()

Return the current shape polygon as tuple of coordinate pairs. This can be used to define a new shape or components of a compound shape.

```
>>> turtle.shape("square")
>>> turtle.shapetransform(4, -1, 0, 2)
>>> turtle.get_shapepoly()
((50, -20), (30, 20), (-50, 20), (-30, -20))
```

Using events

turtle.onclick(*fun*, *btn=1*, *add=None*)

Parameters

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – `True` or `False` – if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this turtle. If *fun* is `None`, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:

```
>>> def turn(x, y):
...     left(180)
...
>>> onclick(turn)  # Now clicking into the turtle w
>>> onclick(None)  # event-binding will be removed
```

turtle.onrelease(*fun*, *btn=1*, *add=None*)

Parameters

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – `True` or `False` – if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-button-release events on this turtle. If *fun* is `None`, existing bindings are removed.

```
>>> class MyTurtle(Turtle):
...     def glow(self,x,y):
...         self.fillcolor("red")
...     def unglow(self,x,y):
...         self.fillcolor("")
...
>>> turtle = MyTurtle()
>>> turtle.onclick(turtle.glow)     # clicking on t
>>> turtle.onrelease(turtle.unglow) # releasing tur
```

turtle.ondrag(*fun*, *btn=1*, *add=None*)

Parameters

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – `True` or `False` – if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-move events on this turtle. If *fun* is `None`, existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

```
>>> turtle.ondrag(turtle.goto)
```

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing handdrawings (if pen is down).

Special Turtle methods

turtle.begin_poly()

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

turtle.end_poly()

Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

turtle.get_poly()

Return the last recorded polygon.

```
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
>>> register_shape("myFavouriteShape", p)
```

turtle.clone()

Create and return a clone of the turtle with same position, heading and turtle properties.

```
>>> mick = Turtle()
>>> joe = mick.clone()
```

turtle.getturtle()

turtle.getpen()

Return the Turtle object itself. Only reasonable use: as a function to return the “anonymous turtle”:

```
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x...>
```

turtle.getscreen()

Return the **TurtleScreen** object the turtle is drawing on. TurtleScreen methods can then be called for that object.

```
>>> ts = turtle.getscreen()
>>> ts
<turtle._Screen object at 0x...>
>>> ts.bgcolor("pink")
```

turtle.setundobuffer(*size*)

Parameters

size – an integer or `None`

Set or disable undobuffer. If *size* is an integer, an empty undobuffer of given size is installed. *size* gives the maximum number of turtle actions that can be undone by the **undo()** method/function. If *size* is `None`, the undobuffer is disabled.

```
>>> turtle.setundobuffer(42)
```

turtle.undobufferentries()

Return number of entries in the undobuffer.

```
>>> while undobufferentries():
```

```
...       undo()
```

Compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class **`Shape`** explicitly as described below:

1. Create an empty Shape object of type “compound”.
2. Add as many components to this object as desired, using the **`addcomponent()`** method.

   For example:

   ```
   >>> s = Shape("compound")
   >>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))
   >>> s.addcomponent(poly1, "red", "blue")
   >>> poly2 = ((0,0),(10,-5),(-10,-5))
   >>> s.addcomponent(poly2, "blue", "red")
   ```

3. Now add the Shape to the Screen’s shapelist and use it:

   ```
   >>> register_shape("myshape", s)
   >>> shape("myshape")
   ```

Note

The **`Shape`** class is used internally by the **`register_shape()`** method in different ways. The application programmer has to deal with the Shape class *only* when using compound shapes like shown above!

Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called `screen`.

Window control

turtle.bgcolor(**args*)

Parameters

args – a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers

Set or return background color of the TurtleScreen.

```
>>> screen.bgcolor("orange")
>>> screen.bgcolor()
'orange'
>>> screen.bgcolor("#800080")
>>> screen.bgcolor()
(128.0, 0.0, 128.0)
```

turtle.bgpic(*picname=None*)

Parameters

picname – a string, name of a gif-file or `"nopic"`, or `None`

Set background image or return name of current backgroundimage. If *picname* is a filename, set the corresponding image as background. If *picname* is `"nopic"`, delete background image, if present. If *picname* is `None`, return the filename of the current backgroundimage.

```
>>> screen.bgpic()
'nopic'
>>> screen.bgpic("landscape.gif")
>>> screen.bgpic()
"landscape.gif"
```

turtle.clear()

Note

This TurtleScreen method is available as a global function only under the name `clearscreen`. The global function `clear` is a different one derived from the Turtle method `clear`.

turtle.clearscreen()

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

turtle.reset()

Note

This TurtleScreen method is available as a global function only under the name `resetscreen`. The global function `reset` is another one derived from the Turtle method `reset`.

turtle.resetscreen()

Reset all Turtles on the Screen to their initial state.

turtle.screensize(*canvwidth=None*, *canvheight=None*, *bg=None*)

Parameters

- **canvwidth** – positive integer, new width of canvas in pixels
- **canvheight** – positive integer, new height of canvas in pixels
- **bg** – colorstring or color-tuple, new background color

If no arguments are given, return current (canvaswidth,

canvasheight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```
>>> screen.screensize()
(400, 300)
>>> screen.screensize(2000,1500)
>>> screen.screensize()
(2000, 1500)
```

e.g. to search for an erroneously escaped turtle ;-)

turtle.setworldcoordinates(*llx*, *lly*, *urx*, *ury*)

Parameters

- **llx** – a number, x-coordinate of lower left corner of canvas
- **lly** – a number, y-coordinate of lower left corner of canvas
- **urx** – a number, x-coordinate of upper right corner of canvas
- **ury** – a number, y-coordinate of upper right corner of canvas

Set up user-defined coordinate system and switch to mode “world” if necessary. This performs a `screen.reset()`. If mode “world” is already active, all drawings are redrawn according to the new coordinates.

ATTENTION: in user-defined coordinate systems angles may appear distorted.

```
>>> screen.reset()
>>> screen.setworldcoordinates(-50,-7.5,50,7.5)
>>> for _ in range(72):
...     left(10)
...
>>> for _ in range(8):
```

```
...     left(45); fd(2)   # a regular octagon
```

Animation control

turtle.delay(*delay* = *None*)

Parameters

delay – positive integer

Set or return the drawing *delay* in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

```
>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5
```

turtle.tracer(*n* = *None*, *delay* = *None*)

Parameters

- **n** – nonnegative integer
- **delay** – nonnegative integer

Turn turtle animation on/off and set delay for update drawings. If *n* is given, only each n-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) When called without arguments, returns the currently stored value of n. Second argument sets delay value (see **`delay()`**).

```
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...     fd(dist)
```

```
...       rt(90)
...       dist += 2
```

turtle.update()

Perform a TurtleScreen update. To be used when tracer is turned off.

See also the RawTurtle/Turtle method **speed()**.

Using screen events

turtle.listen(*xdummy* = *None*, *ydummy* = *None*)

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass **listen()** to the onclick method.

turtle.onkey(*fun*, *key*)
turtle.onkeyrelease(*fun*, *key*)

Parameters

- **fun** – a function with no arguments or `None`
- **key** – a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind *fun* to key-release event of key. If *fun* is `None`, event bindings are removed. Remark: in order to be able to register key-events, TurtleScreen must have the focus. (See method **listen()**.)

```
>>> def f():
...     fd(50)
...     lt(60)
...
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

turtle.onkeypress(*fun*, *key* = *None*)

Parameters

- **fun** – a function with no arguments or `None`
- **key** – a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind *fun* to key-press event of key if key is given, or to any key-press-event if no key is given. Remark: in order to be able to register key-events, TurtleScreen must have focus. (See method **`listen()`**.)

```
>>> def f():
...     fd(50)
...
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

turtle.onclick(*fun*, *btn=1*, *add=None*)
turtle.onscreenclick(*fun*, *btn=1*, *add=None*)

Parameters

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – `True` or `False` – if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this screen. If *fun* is `None`, existing bindings are removed.

Example for a TurtleScreen instance named `screen` and a Turtle instance named `turtle`:

```
>>> screen.onclick(turtle.goto) # Subsequently clic
>>>                             # make the turtle m
```

```
>>> screen.onclick(None)        # remove event bind
```

Note

This TurtleScreen method is available as a global function only under the name `onscreenclick`. The global function `onclick` is another one derived from the Turtle method `onclick`.

turtle.ontimer(*fun*, *t=0*)

Parameters

- **fun** – a function with no arguments
- **t** – a number >= 0

Install a timer that calls *fun* after *t* milliseconds.

```
>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...         screen.ontimer(f, 250)
>>> f()   ### makes the turtle march around
>>> running = False
```

turtle.mainloop()
turtle.done()

Starts event loop - calling Tkinter's mainloop function. Must be the last statement in a turtle graphics program. Must *not* be used if a script is run from within IDLE in -n mode (No subprocess) - for interactive use of turtle graphics.

```
>>> screen.mainloop()
```

Input methods

turtle.textinput(*title*, *prompt*)

Parameters

- **title** – string
- **prompt** – string

Pop up a dialog window for input of a string. Parameter title is the title of the dialog window, prompt is a text mostly describing what information to input. Return the string input. If the dialog is canceled, return `None`.

```
>>> screen.textinput("NIM", "Name of first player:"
```

turtle.numinput(*title*, *prompt*, *default=None*, *minval=None*, *maxval=None*)

Parameters

- **title** – string
- **prompt** – string
- **default** – number (optional)
- **minval** – number (optional)
- **maxval** – number (optional)

Pop up a dialog window for input of a number. title is the title of the dialog window, prompt is a text mostly describing what numerical information to input. default: default value, minval: minimum value for input, maxval: maximum value for input. The number input must be in the range minval .. maxval if these are given. If not, a hint is issued and the dialog remains open for correction. Return the number input. If the dialog is canceled, return `None`.

```
>>> screen.numinput("Poker", "Your stakes:", 1000, 
```

Settings and special methods

turtle.mode(*mode=None*)

Parameters

mode – one of the strings “standard”, “logo” or “world”

Set turtle mode (“standard”, “logo” or “world”) and perform reset. If mode is not given, current mode is returned.

Mode “standard” is compatible with old `turtle`. Mode “logo” is compatible with most Logo turtle graphics. Mode “world” uses user-defined “world coordinates”. **Attention**: in this mode angles appear distorted if `x/y` unit-ratio doesn’t equal 1.

Mode	Initial turtle heading
“standard”	to the right (east)
“logo”	upwards (north)

```
>>> mode("logo")   # resets turtle heading to north
>>> mode()
'logo'
```

turtle.colormode(*cmode=None*)

Parameters

cmode – one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently *r*, *g*, *b* values of color triples have to be in the range 0..*cmode*.

```
>>> screen.colormode(1)
>>> turtle.pencolor(240, 160, 80)
Traceback (most recent call last):
     ...
TurtleGraphicsError: bad color sequence: (240, 160,
>>> screen.colormode()
1.0
>>> screen.colormode(255)
>>> screen.colormode()
255
>>> turtle.pencolor(240,160,80)
```

turtle.getcanvas()

Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```
>>> cv = screen.getcanvas()
>>> cv
<turtle.ScrolledCanvas object ...>
```

turtle.getshapes()

Return a list of names of all currently available turtle shapes.

```
>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

turtle.register_shape(*name*, *shape*=*None*)
turtle.addshape(*name*, *shape*=*None*)

There are three different ways to call this function:

1. *name* is the name of a gif-file and *shape* is `None`: Install the corresponding image shape.

   ```
   >>> screen.register_shape("turtle.gif")
   ```

   Note

   Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

2. *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates: Install the corresponding polygon shape.

   ```
   >>> screen.register_shape("triangle", ((5,-3),
   ```

3. *name* is an arbitrary string and *shape* is a (compound) **`Shape`** object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen's shapelist. Only thusly registered shapes can be used by issuing the command

```
shape(shapename).
```

turtle.turtles()

Return the list of turtles on the screen.

```
>>> for turtle in screen.turtles():
...     turtle.color("red")
```

turtle.window_height()

Return the height of the turtle window.

```
>>> screen.window_height()
480
```

turtle.window_width()

Return the width of the turtle window.

```
>>> screen.window_width()
640
```

Methods specific to Screen, not inherited from TurtleScreen

turtle.bye()

Shut the turtlegraphics window.

turtle.exitonclick()

Bind `bye()` method to mouse clicks on the Screen.

If the value “using_IDLE” in the configuration dictionary is `False` (default value), also enter mainloop. Remark: If IDLE with the `-n` switch (no subprocess) is used, this value should be set to `True` in `turtle.cfg`. In this case IDLE’s own mainloop is active also for the client script.

turtle.setup(*width=_CFG['width']*, *height=_CFG['height']*, *startx=_CFG['leftright']*, *starty=_CFG['topbottom']*)

Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a `turtle.cfg` file.

Parameters

- **width** – if an integer, a size in pixels, if a float, a fraction of the screen; default is 50% of screen
- **height** – if an integer, the height in pixels, if a float, a fraction of the screen; default is 75% of screen
- **startx** – if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if `None`, center window horizontally
- **starty** – if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if `None`, center window vertically

```
>>> screen.setup (width=200, height=200, startx=0,
>>>               # sets window to 200x200 pixels, i
>>> screen.setup(width=.75, height=0.5, startx=None
>>>               # sets window to 75% of screen by
```

turtle.title(*titlestring*)

Parameters

titlestring – a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to *titlestring*.

```
>>> screen.title("Welcome to the turtle zoo!")
```

Public classes

class turtle.RawTurtle(*canvas*)
class turtle.RawPen(*canvas*)

Parameters

canvas – a **tkinter.Canvas**, a **ScrolledCanvas** or a **TurtleScreen**

Create a turtle. The turtle has all methods described above as "methods of Turtle/RawTurtle".

class turtle.Turtle

Subclass of RawTurtle, has the same interface but draws on a default **Screen** object created automatically when needed for the first time.

class turtle.TurtleScreen(*cv*)

Parameters

cv – a **tkinter.Canvas**

Provides screen oriented methods like **setbg()** etc. that are described above.

class turtle.Screen

Subclass of TurtleScreen, with four methods added.

class turtle.ScrolledCanvas(*master*)

Parameters

master – some Tkinter widget to contain the ScrolledCanvas, i.e. a Tkinter-canvas with scrollbars added

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.

class turtle.Shape(*type_*, *data*)

Parameters

type_ – one of the strings "polygon", "image", "compound"

Data structure modeling shapes. The pair `(type_, data)` must follow this specification:

*type_*	*data*
"polygon"	a polygon-tuple, i.e. a tuple of pairs of coordinates
"image"	an image (in this form only used internally!)
"compound"	`None` (a compound shape has to be constructed using the **`addcomponent()`** method)

addcomponent(*poly*, *fill*, *outline*=*None*)

Parameters

- **poly** – a polygon, i.e. a tuple of pairs of numbers
- **fill** – a color the *poly* will be filled with
- **outline** – a color for the poly's outline (if given)

Example:

```
>>> poly = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
>>> # ... add more components and then use regi
```

See Compound shapes.

class turtle.Vec2D(*x*, *y*)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics programs too. Derived from tuple, so a vector is a tuple!

Provides (for *a*, *b* vectors, *k* number):

- `a + b` vector addition
- `a - b` vector subtraction
- `a * b` inner product
- `k * a` and `a * k` multiplication with scalar

- `abs(a)` absolute value of a
- `a.rotate(angle)` rotation

Help and configuration

How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.
- Calling **`help()`** on methods or functions displays the docstrings:

```
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:

bgcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScre

    Arguments (if given): a color string or three n
    in the range 0..colormode or a 3-tuple of such

      >>> screen.bgcolor("orange")
      >>> screen.bgcolor()
      "orange"
      >>> screen.bgcolor(0.5,0,0.5)
      >>> screen.bgcolor()
      "#800080"

>>> help(Turtle.penup)
Help on method penup in module turtle:

penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.
```

```
    Aliases: penup | pu | up

    No argument

    >>> turtle.penup()
```

- The docstrings of the functions which are derived from methods have a modified form:

```
>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
    Set or return backgroundcolor of the TurtleScre

    Arguments (if given): a color string or three n
    in the range 0..colormode or a 3-tuple of such

    Example::

      >>> bgcolor("orange")
      >>> bgcolor()
      "orange"
      >>> bgcolor(0.5,0,0.5)
      >>> bgcolor()
      "#800080"

>>> help(penup)
Help on function penup in module turtle:

penup()
    Pull the pen up -- no drawing when moving.

    Aliases: penup | pu | up

    No argument

    Example:
```

```
>>> penup()
```

These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

turtle.write_docstringdict(*filename='turtle_docstringdict'*)

Parameters

filename – a string, used as filename

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script *filename*`.py`. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use **`turtle`** with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. `turtle_docstringdict_german.py`.

If you have an appropriate entry in your `turtle.cfg` file this dictionary will be read in at import time and will replace the original English docstrings.

At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

How to configure Screen and Turtles

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following turtle.cfg:

```
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
title = Python Turtle Graphics
using_IDLE = False
```

Short explanation of selected entries:

- The first four lines correspond to the arguments of the **`Screen.setup()`** method.
- Line 5 and 6 correspond to the arguments of the method **`Screen.screensize()`**.
- *shape* can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all

nonempty strings must not have quotes in the cfg-file).

- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as **`turtle`**).
- The entries *exampleturtle* and *examplescreen* define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- *using_IDLE*: Set this to `True` if you regularly work with IDLE and its `-n` switch ("no subprocess"). This will prevent **`exitonclick()`** to enter the mainloop.

There can be a `turtle.cfg` file in the directory where **`turtle`** is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The `Lib/turtledemo` directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the demos (preferably not from within the demo-viewer).

`turtledemo` — Demo scripts

The **`turtledemo`** package includes a set of demo scripts. These scripts can be run and viewed using the supplied demo viewer as follows:

```
python -m turtledemo
```

Alternatively, you can run the demo scripts individually. For example,

```
python -m turtledemo.bytedesign
```

The **`turtledemo`** package directory contains:

- A demo viewer `__main__.py` which can be used to view the sourcecode of the scripts and run them at the same time.

- Multiple scripts demonstrating different features of the `turtle` module. Examples can be accessed via the Examples menu. They can also be run standalone.
- A `turtle.cfg` file which serves as an example of how to write and use such files.

The demo scripts are:

Name	Description
bytedesign	complex classical turtle graphics pattern
chaos	graphs Verhulst dynamics, shows that computer's computations can generate results sometimes against the common sense expectations
clock	analog clock showing time of your computer
colormixer	experiment with r, g, b
forest	depth first trees
fractal	fractal dragon, Hilbert & Koch curves
lindenmayer	ethnomathematics (indian kolams)
minimal_hanoi	Towers of Hanoi with Turtles as Hanoi discs (shape, shapesize)
nim	play the classical nim game with three heaps of sticks against the computer.
paint	simple drawing program
peace	elementary turtle: appearance and animation
penrose	aperiodic tiling with kites and darts
planet_and_moon	simulation of gravitational system
rosette	a display of geometric patterns
round_dance	dancing turtles rotating pairwise in opposite direction
sorting_animate	visual demonstration of different sorting methods
tdemo_about_turtle.cfg	demo how to use a configuration file
tdemo_fractalcurves	Hilbert & Koch curves
tdemo_nim	play nim against the computer
tdemo_paint.cfg	example paint program
tdemo_peace.cfg	elementary turtle: appearance and animation
tdemo_penrose.cfg	aperiodic tiling with kites and darts
tdemo_planet_and_moon.cfg	simulation of gravitational system
tdemo_rosette.cfg	a display of geometric patterns
tdemo_round_dance.cfg	dancing turtles rotating pairwise in opposite direction
tdemo_sorting_animate.cfg	visual demonstration of different sorting methods
tdemo_tree	(animated) breadth first tree (using generators)
tdemo_two_canvases	simple design on two canvases
tdemo_wikipedia.cfg	a pattern from the wikipedia article on turtle graphics
tdemo_yinyang	another elementary example

Have fun!

Changes since Python 2.6

- The methods **`Turtle.tracer()`**, **`Turtle.window_width()`** and **`Turtle.window_height()`** have been eliminated. Methods with these names and functionality are now available only as

methods of **Screen**. The functions derived from these remain available. (In fact already in Python 2.6 these methods were merely duplications of the corresponding **TurtleScreen**/**Screen**-methods.)

- The method **Turtle.fill()** has been eliminated. The behaviour of **begin_fill()** and **end_fill()** have changed slightly: now every filling-process must be completed with an `end_fill()` call.
- A method **Turtle.filling()** has been added. It returns a boolean value: `True` if a filling process is under way, `False` otherwise. This behaviour corresponds to a `fill()` call without arguments in Python 2.6.

Changes since Python 3.0

- The methods **Turtle.shearfactor()**, **Turtle.shapetransform()** and **Turtle.get_shapepoly()** have been added. Thus the full range of regular linear transforms is now available for transforming turtle shapes. **Turtle.tiltangle()** has been enhanced in functionality: it now can be used to get or set the tiltangle. **Turtle.settiltangle()** has been deprecated.
- The method **Screen.onkeypress()** has been added as a complement to **Screen.onkey()** which in fact binds actions to the keyrelease event. Accordingly the latter has got an alias: **Screen.onkeyrelease()**.
- The method **Screen.mainloop()** has been added. So when working only with Screen and Turtle objects one must not additionally import **mainloop()** anymore.
- Two input methods has been added **Screen.textinput()** and **Screen.numinput()**. These popup input dialogs and return strings and numbers respectively.
- Two example scripts `tdemo_nim.py` and `tdemo_round_dance.py` have been added to the `Lib/turtledemo` directory.

cmd — Support for line-oriented command interpreters

Source code: Lib/cmd.py [https://github.com/python/cpython/tree/3.11/Lib/cmd.py]

The **Cmd** class provides a simple framework for writing line-oriented command interpreters. These are often useful for test harnesses, administrative tools, and prototypes that will later be wrapped in a more sophisticated interface.

class cmd.Cmd(*completekey='tab'*, *stdin=None*, *stdout=None*)

A **Cmd** instance or subclass instance is a line-oriented interpreter framework. There is no good reason to instantiate **Cmd** itself; rather, it's useful as a superclass of an interpreter class you define yourself in order to inherit **Cmd**'s methods and encapsulate action methods.

The optional argument *completekey* is the **readline** name of a completion key; it defaults to `Tab`. If *completekey* is not **None** and **readline** is available, command completion is done automatically.

The optional arguments *stdin* and *stdout* specify the input and output file objects that the Cmd instance or subclass instance will use for input and output. If not specified, they will default to **sys.stdin** and **sys.stdout**.

If you want a given *stdin* to be used, make sure to set the instance's **use_rawinput** attribute to `False`, otherwise *stdin* will be ignored.

Cmd Objects

A **Cmd** instance has the following methods:

Cmd.cmdloop(*intro*=*None*)

Repeatedly issue a prompt, accept input, parse an initial prefix off the received input, and dispatch to action methods, passing them the remainder of the line as argument.

The optional argument is a banner or intro string to be issued before the first prompt (this overrides the **intro** class attribute).

If the **readline** module is loaded, input will automatically inherit **bash**-like history-list editing (e.g. `Control-P` scrolls back to the last command, `Control-N` forward to the next one, `Control-F` moves the cursor to the right non-destructively, `Control-B` moves the cursor to the left non-destructively, etc.).

An end-of-file on input is passed back as the string `'EOF'`.

An interpreter instance will recognize a command name `foo` if and only if it has a method **do_foo()**. As a special case, a line beginning with the character `'?'` is dispatched to the method **do_help()**. As another special case, a line beginning with the character `'!'` is dispatched to the method **do_shell()** (if such a method is defined).

This method will return when the **postcmd()** method returns a true value. The *stop* argument to **postcmd()** is the return value from the command's corresponding **do_*()** method.

If completion is enabled, completing commands will be done automatically, and completing of commands args is done by calling **complete_foo()** with arguments *text*, *line*, *begidx*, and *endidx*. *text* is the string prefix we are attempting to match: all returned matches must begin with it. *line* is the current input line with leading whitespace removed, *begidx* and *endidx* are the beginning and ending indexes of the prefix text, which could be used to provide different completion depending upon which position the argument is in.

All subclasses of **Cmd** inherit a predefined **do_help()**. This method, called with an argument `'bar'`, invokes the corresponding method **help_bar()**, and if that is not present, prints the docstring of **do_bar()**, if available. With no argument, **do_help()** lists all available help topics (that is, all commands with corresponding **help_*()** methods or commands that have docstrings), and also lists any undocumented commands.

Cmd.onecmd(*str*)

Interpret the argument as though it had been typed in response to the prompt. This may be overridden, but should not normally need to be; see the **precmd()** and **postcmd()** methods for useful execution hooks. The return value is a flag indicating whether interpretation of commands by the interpreter should stop. If there is a **do_*()** method for the command *str*, the return value of that method is returned, otherwise the return value from the **default()** method is returned.

Cmd.emptyline()

Method called when an empty line is entered in response to the prompt. If this method is not overridden, it repeats the last nonempty command entered.

Cmd.default(*line*)

Method called on an input line when the command prefix is not recognized. If this method is not overridden, it prints an error message and returns.

Cmd.completedefault(*text*, *line*, *begidx*, *endidx*)

Method called to complete an input line when no command-specific **complete_*()** method is available. By default, it returns an empty list.

Cmd.columnize(*list*, *displaywidth*=*80*)

Method called to display a list of strings as a compact set of

columns. Each column is only as wide as necessary. Columns are separated by two spaces for readability.

Cmd.precmd(*line*)

Hook method executed just before the command line *line* is interpreted, but after the input prompt is generated and issued. This method is a stub in **Cmd**; it exists to be overridden by subclasses. The return value is used as the command which will be executed by the **onecmd()** method; the **precmd()** implementation may re-write the command or simply return *line* unchanged.

Cmd.postcmd(*stop*, *line*)

Hook method executed just after a command dispatch is finished. This method is a stub in **Cmd**; it exists to be overridden by subclasses. *line* is the command line which was executed, and *stop* is a flag which indicates whether execution will be terminated after the call to **postcmd()**; this will be the return value of the **onecmd()** method. The return value of this method will be used as the new value for the internal flag which corresponds to *stop*; returning false will cause interpretation to continue.

Cmd.preloop()

Hook method executed once when **cmdloop()** is called. This method is a stub in **Cmd**; it exists to be overridden by subclasses.

Cmd.postloop()

Hook method executed once when **cmdloop()** is about to return. This method is a stub in **Cmd**; it exists to be overridden by subclasses.

Instances of **Cmd** subclasses have some public instance variables:

Cmd.prompt

The prompt issued to solicit input.

Cmd.identchars

The string of characters accepted for the command prefix.

Cmd.lastcmd

The last nonempty command prefix seen.

Cmd.cmdqueue

A list of queued input lines. The cmdqueue list is checked in **`cmdloop()`** when new input is needed; if it is nonempty, its elements will be processed in order, as if entered at the prompt.

Cmd.intro

A string to issue as an intro or banner. May be overridden by giving the **`cmdloop()`** method an argument.

Cmd.doc_header

The header to issue if the help output has a section for documented commands.

Cmd.misc_header

The header to issue if the help output has a section for miscellaneous help topics (that is, there are **`help_*()`** methods without corresponding **`do_*()`** methods).

Cmd.undoc_header

The header to issue if the help output has a section for undocumented commands (that is, there are **`do_*()`** methods without corresponding **`help_*()`** methods).

Cmd.ruler

The character used to draw separator lines under the help-message headers. If empty, no ruler line is drawn. It defaults to `'='`.

Cmd.use_rawinput

A flag, defaulting to true. If true, **`cmdloop()`** uses **`input()`**

to display a prompt and read the next command; if false, **`sys.stdout.write()`** and **`sys.stdin.readline()`** are used. (This means that by importing **`readline`**, on systems that support it, the interpreter will automatically support **Emacs**-like line editing and command-history keystrokes.)

Cmd Example

The **`cmd`** module is mainly useful for building custom shells that let a user work with a program interactively.

This section presents a simple example of how to build a shell around a few of the commands in the **`turtle`** module.

Basic turtle commands such as **`forward()`** are added to a **`Cmd`** subclass with method named **`do_forward()`**. The argument is converted to a number and dispatched to the turtle module. The docstring is used in the help utility provided by the shell.

The example also includes a basic record and playback facility implemented with the **`precmd()`** method which is responsible for converting the input to lowercase and writing the commands to a file. The **`do_playback()`** method reads the file and adds the recorded commands to the **`cmdqueue`** for immediate playback:

```
import cmd, sys
from turtle import *

class TurtleShell(cmd.Cmd):
    intro = 'Welcome to the turtle shell.   Type help or
    prompt = '(turtle) '
    file = None

    # ----- basic turtle commands -----
    def do_forward(self, arg):
        'Move the turtle forward by the specified distar
        forward(*parse(arg))
    def do_right(self, arg):
        'Turn turtle right by given number of degrees:
```

```
        right(*parse(arg))
    def do_left(self, arg):
        'Turn turtle left by given number of degrees:  I
        left(*parse(arg))
    def do_goto(self, arg):
        'Move turtle to an absolute position with changi
        goto(*parse(arg))
    def do_home(self, arg):
        'Return turtle to the home position:  HOME'
        home()
    def do_circle(self, arg):
        'Draw circle with given radius an options extent
        circle(*parse(arg))
    def do_position(self, arg):
        'Print the current turtle position:  POSITION'
        print('Current position is %d %d\n' % position()
    def do_heading(self, arg):
        'Print the current turtle heading in degrees:  H
        print('Current heading is %d\n' % (heading(),))
    def do_color(self, arg):
        'Set the color:  COLOR BLUE'
        color(arg.lower())
    def do_undo(self, arg):
        'Undo (repeatedly) the last turtle action(s):  U
    def do_reset(self, arg):
        'Clear the screen and return turtle to center:
        reset()
    def do_bye(self, arg):
        'Stop recording, close the turtle window, and ex
        print('Thank you for using Turtle')
        self.close()
        bye()
        return True

    # ----- record and playback -----
    def do_record(self, arg):
        'Save future commands to filename:  RECORD rose.
        self.file = open(arg, 'w')
```

```
    def do_playback(self, arg):
        'Playback commands from a file:  PLAYBACK rose.c
        self.close()
        with open(arg) as f:
            self.cmdqueue.extend(f.read().splitlines())
    def precmd(self, line):
        line = line.lower()
        if self.file and 'playback' not in line:
            print(line, file=self.file)
        return line
    def close(self):
        if self.file:
            self.file.close()
            self.file = None

def parse(arg):
    'Convert a series of zero or more numbers to an argu
    return tuple(map(int, arg.split()))

if __name__ == '__main__':
    TurtleShell().cmdloop()
```

Here is a sample session with the turtle shell showing the help functions, using blank lines to repeat commands, and the simple record and playback facility:

```
Welcome to the turtle shell.   Type help or ? to list co

(turtle) ?

Documented commands (type help <topic>):
========================================
bye     color    goto     home  playback  record  right
circle  forward  heading  left  position  reset   undo

(turtle) help forward
Move the turtle forward by the specified distance:  FORW
(turtle) record spiral.cmd
(turtle) position
```

```
Current position is 0 0

```

shlex — Simple lexical analysis

Source code: Lib/shlex.py [https://github.com/python/cpython/tree/3.11/Lib/shlex.py]

The shlex class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

The shlex module defines the following functions:

shlex.split(*s*, *comments*=*False*, *posix*=*True*)

Split the string *s* using shell-like syntax. If *comments* is False (the default), the parsing of comments in the given string will be disabled (setting the commenters attribute of the shlex instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the *posix* argument is false.

Note

Since the split() function instantiates a shlex instance, passing None for *s* will read the string to split from standard input.

Deprecated since version 3.9: Passing None for *s* will raise an exception in future Python versions.

shlex.join(*split_command*)

Concatenate the tokens of the list *split_command* and return a string. This function is the inverse of split().

```
>>> from shlex import join
>>> print(join(['echo', '-n', 'Multiple words']))
echo -n 'Multiple words'
```

The returned value is shell-escaped to protect against injection vulnerabilities (see **`quote()`**).

New in version 3.8.

shlex.quote(*s*)

Return a shell-escaped version of the string *s*. The returned value is a string that can safely be used as one token in a shell command line, for cases where you cannot use a list.

Warning

The `shlex` module is **only designed for Unix shells**.

The **`quote()`** function is not guaranteed to be correct on non-POSIX compliant shells or shells from other operating systems such as Windows. Executing commands quoted by this module on such shells can open up the possibility of a command injection vulnerability.

Consider using functions that pass command arguments with lists such as **`subprocess.run()`** with `shell=False`.

This idiom would be unsafe:

```
>>> filename = 'somefile; rm -rf ~'
>>> command = 'ls -l {}'.format(filename)
>>> print(command)  # executed by a shell: boom!
ls -l somefile; rm -rf ~
```

`quote()` lets you plug the security hole:

```
>>> from shlex import quote
>>> command = 'ls -l {}'.format(quote(filename))
>>> print(command)
```

```
ls -l 'somefile; rm -rf ~'
>>> remote_command = 'ssh home {}'.format(quote(com
>>> print(remote_command)
ssh home 'ls -l '"'"'somefile; rm -rf ~'"'"''
```

The quoting is compatible with UNIX shells and with **split()**:

```
>>> from shlex import split
>>> remote_command = split(remote_command)
>>> remote_command
['ssh', 'home', "ls -l 'somefile; rm -rf ~'"]
>>> command = split(remote_command[-1])
>>> command
['ls', '-l', 'somefile; rm -rf ~']
```

New in version 3.3.

The **shlex** module defines the following class:

class shlex.shlex(*instream=None*, *infile=None*, *posix=False*, *punctuation_chars=False*)

A **shlex** instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with **read()** and **readline()** methods, or a string. If no argument is given, input will be taken from `sys.stdin`. The second optional argument is a filename string, which sets the initial value of the **infile** attribute. If the *instream* argument is omitted or equal to `sys.stdin`, this second argument defaults to “stdin”. The *posix* argument defines the operational mode: when *posix* is not true (default), the **shlex** instance will operate in compatibility mode. When operating in POSIX mode, **shlex** will try to be as close as possible to the POSIX shell parsing rules. The *punctuation_chars* argument provides a way to make the behaviour even closer to how real shells parse. This can take a number of values: the default value, `False`, preserves the behaviour seen under Python 3.5 and earlier. If set to `True`,

then parsing of the characters `()<>|&;` is changed: any run of these characters (considered punctuation characters) is returned as a single token. If set to a non-empty string of characters, those characters will be used as the punctuation characters. Any characters in the **`wordchars`** attribute that appear in *punctuation_chars* will be removed from **`wordchars`**. See Improved Compatibility with Shells for more information. *punctuation_chars* can be set only upon **`shlex`** instance creation and can't be modified later.

Changed in version 3.6: The *punctuation_chars* parameter was added.

See also

Module `configparser`
Parser for configuration files similar to the Windows `.ini` files.

shlex Objects

A **`shlex`** instance has the following methods:

shlex.get_token()
Return a token. If tokens have been stacked using **`push_token()`**, pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, **`eof`** is returned (the empty string `''` in non-POSIX mode, and `None` in POSIX mode).

shlex.push_token(*str*)
Push the argument onto the token stack.

shlex.read_token()
Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of

completeness.)

shlex.sourcehook(*filename*)

When **shlex** detects a source request (see **source** below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as `sys.stdin`), the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor handles `#include "file.h"`).

The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with **open()** called on it to yield the second component. (Note: this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding 'close' hook, but a shlex instance will call the **close()** method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the **push_source()** and **pop_source()** methods.

shlex.push_source(*newstream*, *newfile*=*None*)

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the **sourcehook()** method.

shlex.pop_source()

Pop the last-pushed input source from the input stack. This is

the same method used internally when the lexer reaches EOF on a stacked input stream.

shlex.error_leader(*infile=None*, *lineno=None*)

This method generates an error message leader in the format of a Unix C compiler error label; the format is `'"%s", line %d: '`, where the `%s` is replaced with the name of the current source file and the `%d` with the current input line number (the optional arguments can be used to override these).

This convenience is provided to encourage **shlex** users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of **shlex** subclasses have some public instance variables which either control lexical analysis or can be used for debugging:

shlex.commenters

The string of characters that are recognized as comment beginners. All characters from the comment beginner to end of line are ignored. Includes just `'#'` by default.

shlex.wordchars

The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore. In POSIX mode, the accented characters in the Latin-1 set are also included. If **punctuation_chars** is not empty, the characters `~-./*?=`, which can appear in filename specifications and command line parameters, will also be included in this attribute, and any characters which appear in `punctuation_chars` will be removed from `wordchars` if they are present there. If **whitespace_split** is set to `True`, this will have no effect.

shlex.whitespace

Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

shlex.escape

Characters that will be considered as escape. This will be only used in POSIX mode, and includes just `'\'` by default.

shlex.quotes

Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.) By default, includes ASCII single and double quotes.

shlex.escapedquotes

Characters in **quotes** that will interpret escape characters defined in **escape**. This is only used in POSIX mode, and includes just `'"'` by default.

shlex.whitespace_split

If `True`, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with **shlex**, getting tokens in a similar way to shell arguments. When used in combination with **punctuation_chars**, tokens will be split on whitespace in addition to those characters.

Changed in version 3.8: The **punctuation_chars** attribute was made compatible with the **whitespace_split** attribute.

shlex.infile

The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

shlex.instream

The input stream from which this **shlex** instance is reading characters.

shlex.source

This attribute is `None` by default. If you assign a string to it, that string will be recognized as a lexical-level inclusion

request similar to the `source` keyword in various shells. That is, the immediately following token will be opened as a filename and input will be taken from that stream until EOF, at which point the **`close()`** method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

shlex.debug

If this attribute is numeric and `1` or more, a **`shlex`** instance will print verbose progress output on its behavior. If you need to use this, you can read the module source code to learn the details.

shlex.lineno

Source line number (count of newlines seen so far plus one).

shlex.token

The token buffer. It may be useful to examine this when catching exceptions.

shlex.eof

Token used to determine end of file. This will be set to the empty string (`''`), in non-POSIX mode, and to `None` in POSIX mode.

shlex.punctuation_chars

A read-only property. Characters that will be considered punctuation. Runs of punctuation characters will be returned as a single token. However, note that no semantic validity checking will be performed: for example, '> > >' could be returned as a token, even though it may not be recognised as such by shells.

New in version 3.6.

Parsing Rules

When operating in non-POSIX mode, **shlex** will try to obey to the following rules.

- Quote characters are not recognized within words (`Do"Not"Separate` is parsed as the single word `Do"Not"Separate`);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words (`"Do"Separate` is parsed as `"Do"` and `Separate`);
- If **whitespace_split** is `False`, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is `True`, **shlex** will only split words in whitespaces;
- EOF is signaled with an empty string (`''`);
- It's not possible to parse empty strings, even if quoted.

When operating in POSIX mode, **shlex** will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words (`"Do"Not"Separate"` is parsed as the single word `DoNotSeparate`);
- Non-quoted escape characters (e.g. `'\'`) preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of **escapedquotes** (e.g. `"'"`) preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of **escapedquotes** (e.g. `'"'`) preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in **escape**. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.
- EOF is signaled with a **None** value;
- Quoted empty strings (`''`) are allowed.

Improved Compatibility with Shells

New in version 3.6.

The **shlex** class provides compatibility with the parsing performed by common Unix shells like `bash`, `dash`, and `sh`. To take advantage of this compatibility, specify the `punctuation_chars` argument in the constructor. This defaults to `False`, which preserves pre-3.6 behaviour. However, if it is set to `True`, then parsing of the characters `();<>|&` is changed: any run of these characters is returned as a single token. While this is short of a full parser for shells (which would be out of scope for the standard library, given the multiplicity of shells out there), it does allow you to perform processing of command lines more easily than you could otherwise. To illustrate, you can see the difference in the following snippet:

```
>>> import shlex
>>> text = "a && b; c && d || e; f >'abc'; (def \"ghi\"
>>> s = shlex.shlex(text, posix=True)
>>> s.whitespace_split = True
>>> list(s)
['a', '&&', 'b;', 'c', '&&', 'd', '||', 'e;', 'f', '>ab
>>> s = shlex.shlex(text, posix=True, punctuation_chars
>>> s.whitespace_split = True
>>> list(s)
['a', '&&', 'b', ';', 'c', '&&', 'd', '||', 'e', ';', '
'(', 'def', 'ghi', ')']
```

Of course, tokens will be returned which are not valid for shells, and you'll need to implement your own error checks on the returned tokens.

Instead of passing `True` as the value for the punctuation_chars parameter, you can pass a string with specific characters, which will be used to determine which characters constitute punctuation. For example:

```
>>> import shlex
>>> s = shlex.shlex("a && b || c", punctuation_chars="|"
>>> list(s)
['a', '&', '&', 'b', '||', 'c']
```

Note

When `punctuation_chars` is specified, the **`wordchars`** attribute is augmented with the characters `~-./*?=`. That is because these characters can appear in file names (including wildcards) and command-line arguments (e.g. `--color=auto`). Hence:

```
>>> import shlex
>>> s = shlex.shlex('~/a && b-c --color=auto || d *.py?
...                 punctuation_chars=True)
>>> list(s)
['~/a', '&&', 'b-c', '--color=auto', '||', 'd', '*.py?'
```

However, to match the shell as closely as possible, it is recommended to always use `posix` and **`whitespace_split`** when using **`punctuation_chars`**, which will negate **`wordchars`** entirely.

For best effect, `punctuation_chars` should be set in conjunction with `posix=True`. (Note that `posix=False` is the default for **`shlex`**.)

Graphical User Interfaces with Tk

Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the `tkinter` package, and its extension, the `tkinter.tix` and the `tkinter.ttk` modules.

The `tkinter` package is a thin object-oriented layer on top of Tcl/Tk. To use `tkinter`, you don't need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. `tkinter` is a set of wrappers that implement the Tk widgets as Python classes.

`tkinter`'s chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes: references, tutorials, a book and others. `tkinter` is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. The Python wiki lists several alternative GUI frameworks and tools [https://wiki.python.org/moin/GuiProgramming].

`tkinter` — Python interface to Tcl/Tk

Source code: Lib/tkinter/_init_.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/_init_.py]

The `tkinter` package (“Tk interface”) is the standard Python interface to the Tcl/Tk GUI toolkit. Both Tk and `tkinter` are available on most Unix platforms, including macOS, as well as on Windows systems.

Running `python -m tkinter` from the command line should open a window demonstrating a simple Tk interface, letting you know that `tkinter` is properly installed on your system, and also showing what version of Tcl/Tk is installed, so you can read the Tcl/Tk documentation specific to that version.

Tkinter supports a range of Tcl/Tk versions, built either with or without thread support. The official Python binary release bundles Tcl/Tk 8.6 threaded. See the source code for the `_tkinter` module for more information about supported versions.

Tkinter is not a thin wrapper, but adds a fair amount of its own logic to make the experience more pythonic. This documentation will concentrate on these additions and changes, and refer to the official Tcl/Tk documentation for details that are unchanged.

Note

Tcl/Tk 8.5 (2007) introduced a modern set of themed user interface components along with a new API to use them. Both old and new APIs are still available. Most documentation you will find online still uses the old API and can be woefully outdated.

Architecture

Tcl/Tk is not a single library but rather consists of a few distinct modules, each with separate functionality and its own official documentation. Python's binary releases also ship an add-on module together with it.

Tcl

Tcl is a dynamic interpreted programming language, just like Python. Though it can be used on its own as a general-purpose programming language, it is most commonly embedded into C applications as a scripting engine or an interface to the Tk toolkit. The Tcl library has a C interface to create and manage one or more instances of a Tcl interpreter, run Tcl commands and scripts in those instances, and add custom commands implemented in either Tcl or C. Each interpreter has an event queue, and there are facilities to send events to it and process them. Unlike Python, Tcl's execution model is designed around cooperative multitasking, and Tkinter bridges this difference (see Threading model for details).

Tk

Tk is a Tcl package [https://wiki.tcl-lang.org/37432] implemented in C that adds custom commands to create and manipulate GUI widgets. Each `Tk` object embeds its own Tcl interpreter instance with Tk loaded into it. Tk's widgets are very customizable, though at the cost of a dated appearance. Tk uses Tcl's event queue to generate and process GUI events.

Ttk

Themed Tk (Ttk) is a newer family of Tk widgets that provide a much better appearance on different platforms than many of the classic Tk widgets. Ttk is distributed as part of Tk, starting with Tk version 8.5. Python bindings are provided in a separate module, `tkinter.ttk`.

Internally, Tk and Ttk use facilities of the underlying operating system, i.e., Xlib on Unix/X11, Cocoa on macOS, GDI on Windows.

When your Python application uses a class in Tkinter, e.g., to create a widget, the **tkinter** module first assembles a Tcl/Tk command string. It passes that Tcl command string to an internal **_tkinter** binary module, which then calls the Tcl interpreter to evaluate it. The Tcl interpreter will then call into the Tk and/or Ttk packages, which will in turn make calls to Xlib, Cocoa, or GDI.

Tkinter Modules

Support for Tkinter is spread across several modules. Most applications will need the main **tkinter** module, as well as the **tkinter.ttk** module, which provides the modern themed widget set and API:

```
from tkinter import *
from tkinter import ttk
```

class tkinter.Tk(*screenName=None*, *baseName=None*, *className='Tk'*, *useTk=True*, *sync=False*, *use=None*)

Construct a toplevel Tk widget, which is usually the main window of an application, and initialize a Tcl interpreter for this widget. Each instance has its own associated Tcl interpreter.

The **Tk** class is typically instantiated using all default values. However, the following keyword arguments are currently recognized:

screenName

When given (as a string), sets the **DISPLAY** environment variable. (X11 only)

baseName

Name of the profile file. By default, *baseName* is derived from the program name (`sys.argv[0]`).

className

Name of the widget class. Used as a profile file and also as the name with which Tcl is invoked (*argv0* in *interp*).

useTk

If `True`, initialize the Tk subsystem. The **`tkinter.Tcl()`** function sets this to `False`.

sync

If `True`, execute all X server commands synchronously, so that errors are reported immediately. Can be used for debugging. (X11 only)

use

Specifies the *id* of the window in which to embed the application, instead of it being created as an independent toplevel window. *id* must be specified in the same way as the value for the -use option for toplevel widgets (that is, it has a form like that returned by **`winfo_id()`**).

Note that on some platforms this will only work correctly if *id* refers to a Tk frame or toplevel that has its -container option enabled.

`Tk` reads and interprets profile files, named `.`*`className`*`.tcl` and `.`*`baseName`*`.tcl`, into the Tcl interpreter and calls **`exec()`** on the contents of `.`*`className`*`.py` and `.`*`baseName`*`.py`. The path for the profile files is the **`HOME`** environment variable or, if that isn't defined, then **`os.curdir`**.

tk

The Tk application object created by instantiating **`Tk`**. This provides access to the Tcl interpreter. Each widget that is attached the same instance of **`Tk`** has the same value for its **`tk`** attribute.

master

The widget object that contains this widget. For **Tk**, the *master* is **None** because it is the main window. The terms *master* and *parent* are similar and sometimes used interchangeably as argument names; however, calling **winfo_parent()** returns a string of the widget name whereas **master** returns the object. *parent/child* reflects the tree-like relationship while *master/slave* reflects the container structure.

children

The immediate descendants of this widget as a **dict** with the child widget names as the keys and the child instance objects as the values.

tkinter.Tcl(*screenName=None, baseName=None, className='Tk', useTk=False*)

The **Tcl()** function is a factory function which creates an object much like that created by the **Tk** class, except that it does not initialize the Tk subsystem. This is most often useful when driving the Tcl interpreter in an environment where one doesn't want to create extraneous toplevel windows, or where one cannot (such as Unix/Linux systems without an X server). An object created by the **Tcl()** object can have a Toplevel window created (and the Tk subsystem initialized) by calling its **loadtk()** method.

The modules that provide Tk support include:

tkinter
Main Tkinter module.

tkinter.colorchooser
Dialog to let the user choose a color.

tkinter.commondialog
Base class for the dialogs defined in the other modules listed here.

tkinter.filedialog

Common dialogs to allow the user to specify a file to open or save.

tkinter.font
Utilities to help work with fonts.

tkinter.messagebox
Access to standard Tk dialog boxes.

tkinter.scrolledtext
Text widget with a vertical scroll bar built in.

tkinter.simpledialog
Basic dialogs and convenience functions.

tkinter.ttk
Themed widget set introduced in Tk 8.5, providing modern alternatives for many of the classic widgets in the main **tkinter** module.

Additional modules:

_tkinter
A binary module that contains the low-level interface to Tcl/Tk. It is automatically imported by the main **tkinter** module, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

idlelib
Python's Integrated Development and Learning Environment (IDLE). Based on **tkinter**.

tkinter.constants
Symbolic constants that can be used in place of strings when passing various parameters to Tkinter calls. Automatically imported by the main **tkinter** module.

tkinter.dnd
(experimental) Drag-and-drop support for **tkinter**. This

will become deprecated when it is replaced with the Tk DND.

tkinter.tix
: (deprecated) An older third-party Tcl/Tk package that adds several new widgets. Better alternatives for most can be found in **tkinter.ttk**.

turtle
: Turtle graphics in a Tk window.

Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. For that, refer to one of the external resources noted earlier. Instead, this section provides a very quick orientation to what a Tkinter application looks like, identifies foundational Tk concepts, and explains how the Tkinter wrapper is structured.

The remainder of this section will help you to identify the classes, methods, and options you'll need in your Tkinter application, and where to find more detailed documentation on them, including in the official Tcl/Tk reference manual.

A Hello World Program

We'll start by walking through a "Hello World" application in Tkinter. This isn't the smallest one we could write, but has enough to illustrate some key concepts you'll need to know.

```
from tkinter import *
from tkinter import ttk
root = Tk()
frm = ttk.Frame(root, padding=10)
frm.grid()
ttk.Label(frm, text="Hello World!").grid(column=0, row=0
ttk.Button(frm, text="Quit", command=root.destroy).grid(
root.mainloop()
```

After the imports, the next line creates an instance of the **Tk** class, which initializes Tk and creates its associated Tcl interpreter. It also

creates a toplevel window, known as the root window, which serves as the main window of the application.

The following line creates a frame widget, which in this case will contain a label and a button we'll create next. The frame is fit inside the root window.

The next line creates a label widget holding a static text string. The **`grid()`** method is used to specify the relative layout (position) of the label within its containing frame widget, similar to how tables in HTML work.

A button widget is then created, and placed to the right of the label. When pressed, it will call the **`destroy()`** method of the root window.

Finally, the **`mainloop()`** method puts everything on the display, and responds to user input until the program terminates.

Important Tk Concepts

Even this simple program illustrates the following key Tk concepts:

widgets
: A Tkinter user interface is made up of individual *widgets*. Each widget is represented as a Python object, instantiated from classes like **`ttk.Frame`**, **`ttk.Label`**, and **`ttk.Button`**.

widget hierarchy
: Widgets are arranged in a *hierarchy*. The label and button were contained within a frame, which in turn was contained within the root window. When creating each *child* widget, its *parent* widget is passed as the first argument to the widget constructor.

configuration options
: Widgets have *configuration options*, which modify their appearance and behavior, such as the text to display in a label or button. Different classes of widgets will have different sets of options.

geometry management
: Widgets aren't automatically added to the user interface when they are created. A *geometry manager* like `grid` controls where in the user interface they are placed.

event loop
: Tkinter reacts to user input, changes from your program, and even refreshes the display only when actively running an *event loop*. If your program isn't running the event loop, your user interface won't update.

Understanding How Tkinter Wraps Tcl/Tk

When your application uses Tkinter's classes and methods, internally Tkinter is assembling strings representing Tcl/Tk commands, and executing those commands in the Tcl interpreter attached to your applicaton's `Tk` instance.

Whether it's trying to navigate reference documentation, trying to find the right method or option, adapting some existing code, or debugging your Tkinter application, there are times that it will be useful to understand what those underlying Tcl/Tk commands look like.

To illustrate, here is the Tcl/Tk equivalent of the main part of the Tkinter script above.

```
ttk::frame .frm -padding 10
grid .frm
grid [ttk::label .frm.lbl -text "Hello World!"] -column
grid [ttk::button .frm.btn -text "Quit" -command "destro
```

Tcl's syntax is similar to many shell languages, where the first word is the command to be executed, with arguments to that command following it, separated by spaces. Without getting into too many details, notice the following:

- The commands used to create widgets (like `ttk::frame`) correspond to widget classes in Tkinter.
- Tcl widget options (like `-text`) correspond to keyword arguments in Tkinter.

- Widgets are referred to by a *pathname* in Tcl (like `.frm.btn`), whereas Tkinter doesn't use names but object references.
- A widget's place in the widget hierarchy is encoded in its (hierarchical) pathname, which uses a `.` (dot) as a path separator. The pathname for the root window is just `.` (dot). In Tkinter, the hierarchy is defined not by pathname but by specifying the parent widget when creating each child widget.
- Operations which are implemented as separate *commands* in Tcl (like `grid` or `destroy`) are represented as *methods* on Tkinter widget objects. As you'll see shortly, at other times Tcl uses what appear to be method calls on widget objects, which more closely mirror what would is used in Tkinter.

How do I…? What option does…?

If you're not sure how to do something in Tkinter, and you can't immediately find it in the tutorial or reference documentation you're using, there are a few strategies that can be helpful.

First, remember that the details of how individual widgets work may vary across different versions of both Tkinter and Tcl/Tk. If you're searching documentation, make sure it corresponds to the Python and Tcl/Tk versions installed on your system.

When searching for how to use an API, it helps to know the exact name of the class, option, or method that you're using. Introspection, either in an interactive Python shell or with **`print()`**, can help you identify what you need.

To find out what configuration options are available on any widget, call its **`configure()`** method, which returns a dictionary containing a variety of information about each object, including its default and current values. Use **`keys()`** to get just the names of each option.

```
btn = ttk.Button(frm, ...)
print(btn.configure().keys())
```

As most widgets have many configuration options in common, it can be useful to find out which are specific to a particular widget

class. Comparing the list of options to that of a simpler widget, like a frame, is one way to do that.

```
print(set(btn.configure().keys()) - set(frm.configure().
```

Similarly, you can find the available methods for a widget object using the standard **`dir()`** function. If you try it, you'll see there are over 200 common widget methods, so again identifying those specific to a widget class is helpful.

```
print(dir(btn))
print(set(dir(btn)) - set(dir(frm)))
```

Navigating the Tcl/Tk Reference Manual

As noted, the official Tk commands [https://www.tcl.tk/man/tcl8.6/TkCmd/contents.htm] reference manual (man pages) is often the most accurate description of what specific operations on widgets do. Even when you know the name of the option or method that you need, you may still have a few places to look.

While all operations in Tkinter are implemented as method calls on widget objects, you've seen that many Tcl/Tk operations appear as commands that take a widget pathname as its first parameter, followed by optional parameters, e.g.

```
destroy .
grid .frm.btn -column 0 -row 0
```

Others, however, look more like methods called on a widget object (in fact, when you create a widget in Tcl/Tk, it creates a Tcl command with the name of the widget pathname, with the first parameter to that command being the name of a method to call).

```
.frm.btn invoke
.frm.lbl configure -text "Goodbye"
```

In the official Tcl/Tk reference documentation, you'll find most operations that look like method calls on the man page for a specific widget (e.g., you'll find the **`invoke()`** method on the ttk::button [https://www.tcl.tk/man/tcl8.6/TkCmd/ttk_button.htm] man

page), while functions that take a widget as a parameter often have their own man page (e.g., grid [https://www.tcl.tk/man/tcl8.6/TkCmd/grid.htm]).

You'll find many common options and methods in the options [https://www.tcl.tk/man/tcl8.6/TkCmd/options.htm] or ttk::widget [https://www.tcl.tk/man/tcl8.6/TkCmd/ttk_widget.htm] man pages, while others are found in the man page for a specific widget class.

You'll also find that many Tkinter methods have compound names, e.g., **`winfo_x()`**, **`winfo_height()`**, **`winfo_viewable()`**. You'd find documentation for all of these in the winfo [https://www.tcl.tk/man/tcl8.6/TkCmd/winfo.htm] man page.

Note

Somewhat confusingly, there are also methods on all Tkinter widgets that don't actually operate on the widget, but operate at a global scope, independent of any widget. Examples are methods for accessing the clipboard or the system bell. (They happen to be implemented as methods in the base **`Widget`** class that all Tkinter widgets inherit from).

Threading model

Python and Tcl/Tk have very different threading models, which **`tkinter`** tries to bridge. If you use threads, you may need to be aware of this.

A Python interpreter may have many threads associated with it. In Tcl, multiple threads can be created, but each thread has a separate Tcl interpreter instance associated with it. Threads can also create more than one interpreter instance, though each interpreter instance can be used only by the one thread that created it.

Each **`Tk`** object created by **`tkinter`** contains a Tcl interpreter. It also keeps track of which thread created that interpreter. Calls to **`tkinter`** can be made from any Python thread. Internally, if a call comes from a thread other than the one that created the **`Tk`** object,

an event is posted to the interpreter's event queue, and when executed, the result is returned to the calling Python thread.

Tcl/Tk applications are normally event-driven, meaning that after initialization, the interpreter runs an event loop (i.e. `Tk.mainloop()`) and responds to events. Because it is single-threaded, event handlers must respond quickly, otherwise they will block other events from being processed. To avoid this, any long-running computations should not run in an event handler, but are either broken into smaller pieces using timers, or run in another thread. This is different from many GUI toolkits where the GUI runs in a completely separate thread from all application code including event handlers.

If the Tcl interpreter is not running the event loop and processing events, any `tkinter` calls made from threads other than the one running the Tcl interpreter will fail.

A number of special cases exist:

- Tcl/Tk libraries can be built so they are not thread-aware. In this case, `tkinter` calls the library from the originating Python thread, even if this is different than the thread that created the Tcl interpreter. A global lock ensures only one call occurs at a time.
- While `tkinter` allows you to create more than one instance of a `Tk` object (with its own interpreter), all interpreters that are part of the same thread share a common event queue, which gets ugly fast. In practice, don't create more than one instance of `Tk` at a time. Otherwise, it's best to create them in separate threads and ensure you're running a thread-aware Tcl/Tk build.
- Blocking event handlers are not the only way to prevent the Tcl interpreter from reentering the event loop. It is even possible to run multiple nested event loops or abandon the event loop entirely. If you're doing anything

tricky when it comes to events or threads, be aware of these possibilities.

- There are a few select `tkinter` functions that presently work only when called from the thread that created the Tcl interpreter.

Handy Reference

Setting Options

Options control things like the color and border width of a widget. Options can be set in three ways:

At object creation time, using keyword arguments

```
fred = Button(self, fg="red", bg="blue")
```

After object creation, treating the option name like a dictionary index

```
fred["fg"] = "red"
fred["bg"] = "blue"
```

Use the config() method to update multiple attrs subsequent to object creation

```
fred.config(fg="red", bg="blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list “STANDARD OPTIONS” and “WIDGET SPECIFIC OPTIONS” for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the *options(3)* man page.

No distinction between standard and widget-specific options is made in this document. Some options don’t apply to some kinds of widgets. Whether a given widget responds to a particular option

depends on the class of the widget; buttons have a `command` option, labels do not.

The options supported by a given widget are listed in that widget's man page, or can be queried at runtime by calling the **`config()`** method without arguments, or by calling the **`keys()`** method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, `'relief'`) and whose values are 5-tuples.

Some options, like `bg` are synonyms for common options with long names (`bg` is shorthand for "background"). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not 5-tuple. The 2-tuple passed back will contain the name of the synonym and the "real" option (such as `('bg', 'background')`).

Meaning
Option name
Option name for database lookup
Option class for database lookup
Default value
Current value

Example:

```
>>> print(fred.config())
{'relief': ('relief', 'relief', 'Relief', 'raised', 'gro
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

The Packer

The packer is one of Tk's geometry-management mechanisms. Geometry managers are used to specify the relative positioning of widgets within their container - their mutual *master*. In contrast to the more cumbersome *placer* (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - *above*, *to the left of*, *filling*, etc - and works everything out to determine the exact placement coordinates for you.

The size of any *master* widget is determined by the size of the "slave widgets" inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It's a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer's **`pack()`** method applied to it.

The pack() method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples:

```
fred.pack()                          # defaults to side = "to
fred.pack(side="left")
fred.pack(expand=1)
```

Packer Options

For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout's book.

anchor
: Anchor type. Denotes where the packer is to place each slave in its parcel.

expand
: Boolean, `0` or `1`.

fill
: Legal values: `'x'`, `'y'`, `'both'`, `'none'`.

ipadx and ipady

A distance - designating internal padding on each side of the slave widget.

padx and pady
: A distance - designating external padding on each side of the slave widget.

side
: Legal values are: `'left'`, `'right'`, `'top'`, `'bottom'`.

Coupling Widget Variables

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are `variable`, `textvariable`, `onvalue`, `offvalue`, and `value`. This connection works both ways: if the variable changes for any reason, the widget it's connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of **`tkinter`** it is not possible to hand over an arbitrary Python variable to a widget through a `variable` or `textvariable` option. The only kinds of variables for which this works are variables that are subclassed from a class called Variable, defined in **`tkinter`**.

There are many useful subclasses of Variable already defined: **`StringVar`**, **`IntVar`**, **`DoubleVar`**, and **`BooleanVar`**. To read the current value of such a variable, call the **`get()`** method on it, and to change its value you call the **`set()`** method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

For example:

```
import tkinter as tk

class App(tk.Frame):
    def __init__(self, master):
        super().__init__(master)
        self.pack()
```

```
        self.entrythingy = tk.Entry()
        self.entrythingy.pack()

        # Create the application variable.
        self.contents = tk.StringVar()
        # Set it to some value.
        self.contents.set("this is a variable")
        # Tell the entry widget to watch this variable.
        self.entrythingy["textvariable"] = self.contents

        # Define a callback for when the user hits retur
        # It prints the current value of the variable.
        self.entrythingy.bind('<Key-Return>',
                              self.print_contents)

    def print_contents(self, event):
        print("Hi. The current entry content is:",
              self.contents.get())

root = tk.Tk()
myapp = App(root)
myapp.mainloop()
```

The Window Manager

In Tk, there is a utility command, `wm`, for interacting with the window manager. Options to the `wm` command allow you to control things like titles, placement, icon bitmaps, and the like. In **`tkinter`**, these commands have been implemented as methods on the **`Wm`** class. Toplevel widgets are subclassed from the **`Wm`** class, and so can call the **`Wm`** methods directly.

To get at the toplevel window that contains a given widget, you can often just refer to the widget's master. Of course if the widget has been packed inside of a frame, the master won't represent a toplevel window. To get at the toplevel window that contains an arbitrary widget, you can call the **`_root()`** method. This method begins with an underscore to denote the fact that this function is part of

the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage:

```
import tkinter as tk

class App(tk.Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()

# create the application
myapp = App()

#
# here are method calls to the window manager class
#
myapp.master.title("My Do-Nothing Application")
myapp.master.maxsize(1000, 400)

# start the program
myapp.mainloop()
```

Tk Option Data Types

anchor

Legal values are points of the compass: `"n"`, `"ne"`, `"e"`, `"se"`, `"s"`, `"sw"`, `"w"`, `"nw"`, and also `"center"`.

bitmap

There are eight built-in, named bitmaps: `'error'`, `'gray25'`, `'gray50'`, `'hourglass'`, `'info'`, `'questhead'`, `'question'`, `'warning'`. To specify an X bitmap filename, give the full path to the file, preceded with an `@`, as in `"@/usr/contrib/bitmap/gumby.bit"`.

boolean

You can pass integers 0 or 1 or the strings `"yes"` or `"no"`.

callback

This is any Python function that takes no arguments. For example:

```
def print_it():
    print("hi there")
fred["command"] = print_it
```

color

Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit: `"#RGB"`, 8 bit: `"#RRGGBB"`, 12 bit: `"#RRRGGGBBB"`, or 16 bit: `"#RRRRGGGGBBBB"` ranges, where R,G,B here represent any legal hex digit. See page 160 of Ousterhout's book for details.

cursor

The standard X cursor names from `cursorfont.h` can be used, without the `XC_` prefix. For example to get a hand cursor (**`XC_hand2`**), use the string `"hand2"`. You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

distance

Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units: `c` for centimetres, `i` for inches, `m` for millimetres, `p` for printer's points. For example, 3.5 inches is expressed as `"3.5i"`.

font

Tk uses a list font name format, such as `{courier 10 bold}`. Font sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

geometry

This is a string of the form `widthxheight`, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example: `fred["geometry"] = "200x100"`.

justify

Legal values are the strings: `"left"`, `"center"`, `"right"`, and `"fill"`.

region

This is a string with four space-delimited elements, each of which is a legal distance (see above). For example: `"2 3 4 5"` and `"3i 2i 4.5i 2i"` and `"3c 2c 4c 10.43c"` are all legal regions.

relief

Determines what the border style of a widget will be. Legal values are: `"raised"`, `"sunken"`, `"flat"`, `"groove"`, and `"ridge"`.

scrollcommand

This is almost always the **`set()`** method of some scrollbar widget, but can be any widget method that takes a single argument.

wrap

Must be one of: `"none"`, `"char"`, or `"word"`.

Bindings and Events

The bind method from the widget command allows you to watch for certain events and to have a callback function trigger when that event type occurs. The form of the bind method is:

```
def bind(self, sequence, func, add=''):
```

where:

sequence

is a string that denotes the target kind of event. (See the *bind(3tk)* man page, and page 201 of John Ousterhout's book, *Tcl and the Tk Toolkit (2nd edition)*, for details).

func

is a Python function, taking one argument, to be invoked

when the event occurs. An Event instance will be passed as the argument. (Functions deployed this way are commonly known as *callbacks*.)

add
: is optional, either `''` or `'+'`. Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a `'+'` means that this function is to be added to the list of functions bound to this event type.

For example:

```
def turn_red(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turn_red)
```

Notice how the widget field of the event is being accessed in the `turn_red()` callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

Tkinter Event Field	Tk Substitution
char	%A
delta	%D
height	%h
keycode	%k
keysym	%K
keysym_num	%N
type	%T
widget	%W
x_root	%X
y_root	%Y

The index Parameter

A number of widgets require “index” parameters to be passed. These are used to point at a specific place in a Text widget, or to particular characters in an Entry widget, or to particular menu items in a Menu widget.

Entry widget indexes (index, view index, etc.)
: Entry widgets have options that refer to character positions in the text being displayed. You can use these **`tkinter`** functions to access these special points in text widgets:

Text widget indexes
: The index notation for Text widgets is very rich and is best described in the Tk man pages.

Menu indexes (menu.invoke(), menu.entryconfig(), etc.)
: Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in:

  - an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
  - the string `"active"`, which refers to the menu position that is currently under the cursor;
  - the string `"last"` which refers to the last menu item;
  - An integer preceded by `@`, as in `@6`, where the integer is interpreted as a y pixel coordinate in the menu's coordinate system;
  - the string `"none"`, which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and finally,
  - a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled `last`, `active`, or `none` may be interpreted as the above literals, instead.

Images

Images of different formats can be created through the corresponding subclass of **`tkinter.Image`**:

- **`BitmapImage`** for images in XBM format.
- **`PhotoImage`** for images in PGM, PPM, GIF and PNG formats.

The latter is supported starting with Tk 8.6.

Either type of image is created through either the `file` or the `data` option (other options are available as well).

The image object can then be used wherever an `image` option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.

The Pillow [https://python-pillow.org/] package adds support for formats such as BMP, JPEG, TIFF, and WebP, among others.

File Handlers

Tk allows you to register and unregister a callback function which will be called from the Tk mainloop when I/O is possible on a file descriptor. Only one handler may be registered per file descriptor. Example code:

```
import tkinter
widget = tkinter.Tk()
mask = tkinter.READABLE | tkinter.WRITABLE
widget.tk.createfilehandler(file, mask, callback)
...
widget.tk.deletefilehandler(file)
```

This feature is not available on Windows.

Since you don't know how many bytes are available for reading, you may not want to use the **`BufferedIOBase`** or **`TextIOBase`** **`read()`** or **`readline()`** methods, since these will insist on reading a predefined number of bytes. For sockets, the **`recv()`** or **`recvfrom()`** methods will work fine; for other files, use raw reads or `os.read(file.fileno(), maxbytecount)`.

Widget.tk.createfilehandler(*file*, *mask*, *func*)

Registers the file handler callback function *func*. The *file* argument may either be an object with a `fileno()` method (such as a file or socket object), or an integer file descriptor. The *mask* argument is an ORed combination of any of the three constants below. The callback is called as follows:

```
callback(file, mask)
```

Widget.tk.deletefilehandler(*file*)

Unregisters a file handler.

tkinter.READABLE
tkinter.WRITABLE
tkinter.EXCEPTION

Constants used in the *mask* arguments.

`tkinter.colorchooser` — Color choosing dialog

Source code: Lib/tkinter/colorchooser.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/colorchooser.py]

The `tkinter.colorchooser` module provides the `Chooser` class as an interface to the native color picker dialog. `Chooser` implements a modal color choosing dialog window. The `Chooser` class inherits from the `Dialog` class.

class tkinter.colorchooser.Chooser(*master=None*, ***options*)

tkinter.colorchooser.askcolor(*color=None*, ***options*)

Create a color choosing dialog. A call to this method will show the window, wait for the user to make a selection, and return the selected color (or `None`) to the caller.

Module `tkinter.commondialog`
Tkinter standard dialog module

`tkinter.font` — Tkinter font wrapper

Source code: Lib/tkinter/font.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/font.py]

The `tkinter.font` module provides the `Font` class for creating and using named fonts.

The different font weights and slants are:

tkinter.font.NORMAL
tkinter.font.BOLD
tkinter.font.ITALIC
tkinter.font.ROMAN

class tkinter.font.Font(*root=None*, *font=None*, *name=None*, *exists=False*, ***options*)

The `Font` class represents a named font. *Font* instances are given unique names and can be specified by their family, size, and style configuration. Named fonts are Tk's method of creating and identifying fonts as a single object, rather than specifying a font by its attributes with each occurrence.

arguments:

font - font specifier tuple
(family, size, options)
name - unique font name
exists - self points to existing
named font if true

additional keyword options (ignored if *font* is specified):

family - font family i.e. Courier, Times
size - font size
If *size* is positive it is interpreted as size in points.
If *size* is a negative number its absolute value is treated
as size in pixels.
weight - font emphasis (NORMAL, BOLD)
slant - ROMAN, ITALIC
underline - font underlining (0 - none, 1 - underline)
overstrike - font strikeout (0 - none, 1 - strikeout)

actual(*option=None, displayof=None*)

Return the attributes of the font.

cget(*option*)

Retrieve an attribute of the font.

config(***options*)

Modify attributes of the font.

copy()

Return new instance of the current font.

measure(*text, displayof=None*)

Return amount of space the text would occupy on the specified display when formatted in the current font. If no display is specified then the main application window is assumed.

metrics(**options, **kw*)

Return font-specific data. Options include:

ascent - distance between baseline and highest point that a
character of the font can occupy

descent - distance between baseline and lowest point that a
character of the font can occupy

linespace - minimum vertical separation necessary between any two
characters of the font that ensures no vertical overlap between lines.

fixed - 1 if font is fixed-width else 0

tkinter.font.families(*root=None*, *displayof=None*)

Return the different font families.

tkinter.font.names(*root=None*)

Return the names of defined fonts.

tkinter.font.nametofont(*name*, *root=None*)

Return a `Font` representation of a tk named font.

Changed in version 3.10: The *root* parameter was added.

Tkinter Dialogs

`tkinter.simpledialog` — Standard Tkinter input dialogs

Source code: Lib/tkinter/simpledialog.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/simpledialog.py]

The `tkinter.simpledialog` module contains convenience classes and functions for creating simple modal dialogs to get a value from the user.

tkinter.simpledialog.askfloat(*title*, *prompt*, ***kw*)
tkinter.simpledialog.askinteger(*title*, *prompt*, ***kw*)
tkinter.simpledialog.askstring(*title*, *prompt*, ***kw*)

The above three functions provide dialogs that prompt the user to enter a value of the desired type.

class tkinter.simpledialog.Dialog(*parent*, *title=None*)

The base class for custom dialogs.

body(*master*)

Override to construct the dialog's interface and return the widget that should have initial focus.

buttonbox()

Default behaviour adds OK and Cancel buttons. Override for custom button layouts.

`tkinter.filedialog` — File selection

dialogs

Source code: Lib/tkinter/filedialog.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/filedialog.py]

The **tkinter.filedialog** module provides classes and factory functions for creating file/directory selection windows.

Native Load/Save Dialogs

The following classes and functions provide file dialog windows that combine a native look-and-feel with configuration options to customize behaviour. The following keyword arguments are applicable to the classes and functions listed below:

parent - the window to place the dialog on top of

title - the title of the window

initialdir - the directory that the dialog starts in

initialfile - the file selected upon opening of the dialog

filetypes - a sequence of (label, pattern) tuples, '*' wildcard is allowed

defaultextension - default extension to append to file (save dialogs)

multiple - when true, selection of multiple items is allowed

Static factory functions

The below functions when called create a modal, native look-and-feel dialog, wait for the user's selection, then return the selected value(s) or `None` to the caller.

tkinter.filedialog.askopenfile(*mode='r', **options*)

tkinter.filedialog.askopenfiles(*mode='r', **options*)

The above two functions create an **Open** dialog and return the opened file object(s) in read-only mode.

tkinter.filedialog.asksaveasfile(*mode='w', **options*)

Create a **SaveAs** dialog and return a file object opened in write-only mode.

tkinter.filedialog.askopenfilename(***options*)
tkinter.filedialog.askopenfilenames(***options*)

The above two functions create an **Open** dialog and return the selected filename(s) that correspond to existing file(s).

tkinter.filedialog.asksaveasfilename(***options*)

Create a **SaveAs** dialog and return the selected filename.

tkinter.filedialog.askdirectory(***options*)

Prompt user to select a directory.
Additional keyword option:
mustexist - determines if selection must be an existing directory.

class tkinter.filedialog.Open(*master=None, **options*)
class tkinter.filedialog.SaveAs(*master=None, **options*)

The above two classes provide native dialog windows for saving and loading files.

Convenience classes

The below classes are used for creating file/directory windows from scratch. These do not emulate the native look-and-feel of the platform.

class tkinter.filedialog.Directory(*master=None, **options*)

Create a dialog prompting the user to select a directory.

Note

The *FileDialog* class should be subclassed for custom event handling and behaviour.

class tkinter.filedialog.FileDialog(*master*, *title*=*None*)

Create a basic file selection dialog.

cancel_command(*event*=*None*)

Trigger the termination of the dialog window.

dirs_double_event(*event*)

Event handler for double-click event on directory.

dirs_select_event(*event*)

Event handler for click event on directory.

files_double_event(*event*)

Event handler for double-click event on file.

files_select_event(*event*)

Event handler for single-click event on file.

filter_command(*event*=*None*)

Filter the files by directory.

get_filter()

Retrieve the file filter currently in use.

get_selection()

Retrieve the currently selected item.

go(*dir_or_file*=*os.curdir*, *pattern*='*', *default*='', *key*=*None*)

Render dialog and start event loop.

ok_event(*event*)

Exit dialog returning current selection.

quit(*how=None*)

Exit dialog returning filename, if any.

set_filter(*dir*, *pat*)

Set the file filter.

set_selection(*file*)

Update the current file selection to *file*.

class tkinter.filedialog.LoadFileDialog(*master*, *title=None*)

A subclass of FileDialog that creates a dialog window for selecting an existing file.

ok_command()

Test that a file is provided and that the selection indicates an already existing file.

class tkinter.filedialog.SaveFileDialog(*master*, *title=None*)

A subclass of FileDialog that creates a dialog window for selecting a destination file.

ok_command()

Test whether or not the selection points to a valid file that is not a directory. Confirmation is required if an already existing file is selected.

`tkinter.commondialog` — Dialog window templates

Source code: Lib/tkinter/commondialog.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/commondialog.py]

The **tkinter.commondialog** module provides the **Dialog** class that is the base class for dialogs defined in other supporting modules.

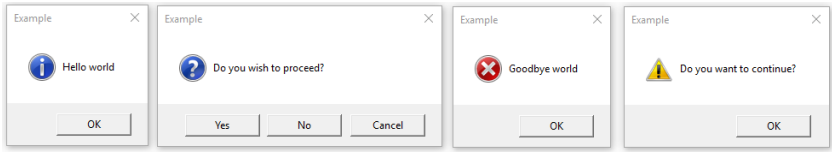
class tkinter.commondialog.Dialog(*master=None*, ***options*)

show(*color=None*, ***options*)

Render the Dialog window.

See also

Modules **tkinter.messagebox**, Reading and Writing Files



`tkinter.messagebox` — Tkinter message prompts

Source code: Lib/tkinter/messagebox.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/messagebox.py]

The `tkinter.messagebox` module provides a template base class as well as a variety of convenience methods for commonly used configurations. The message boxes are modal and will return a subset of (True, False, OK, None, Yes, No) based on the user's selection. Common message box styles and layouts include but are not limited to:

class tkinter.messagebox.Message(*master=None*, ***options*)

Create a default information message box.

Information message box

tkinter.messagebox.showinfo(*title=None*, *message=None*, ***options*)

Warning message boxes

tkinter.messagebox.showwarning(*title=None*, *message=None*, ***options*)
tkinter.messagebox.showerror(*title=None*, *message=None*, ***options*)

Question message boxes

tkinter.messagebox.askquestion(*title=None*, *message=None*,

***options*)
tkinter.messagebox.askokcancel(*title=None*, *message=None*,
***options*)
tkinter.messagebox.askretrycancel(*title=None*, *message=None*,
***options*)
tkinter.messagebox.askyesno(*title=None*, *message=None*, ***options*)
tkinter.messagebox.askyesnocancel(*title=None*, *message=None*,
***options*)

`tkinter.scrolledtext` — Scrolled Text Widget

Source code: Lib/tkinter/scrolledtext.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/scrolledtext.py]

The `tkinter.scrolledtext` module provides a class of the same name which implements a basic text widget which has a vertical scroll bar configured to do the "right thing." Using the `ScrolledText` class is a lot easier than setting up a text widget and scroll bar directly.

The text widget and scrollbar are packed together in a `Frame`, and the methods of the `Grid` and `Pack` geometry managers are acquired from the `Frame` object. This allows the `ScrolledText` widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

class tkinter.scrolledtext.ScrolledText(*master=None*, ***kw*)

frame

The frame which surrounds the text and scroll bar widgets.

vbar

The scroll bar widget.

`tkinter.dnd` — Drag and drop support

Source code: Lib/tkinter/dnd.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/dnd.py]

Note

This is experimental and due to be deprecated when it is replaced with the Tk DND.

The `tkinter.dnd` module provides drag-and-drop support for objects within a single application, within the same window or between windows. To enable an object to be dragged, you must create an event binding for it that starts the drag-and-drop process. Typically, you bind a ButtonPress event to a callback function that you write (see Bindings and Events). The function should call `dnd_start()`, where 'source' is the object to be dragged, and 'event' is the event that invoked the call (the argument to your callback function).

Selection of a target object occurs as follows:

1. Top-down search of area under mouse for target widget
    - Target widget should have a callable *dnd_accept* attribute
    - If *dnd_accept* is not present or returns None, search moves to parent widget
    - If no target widget is found, then the target object is None

1. Call to *<old_target>.dnd_leave(source, event)*
2. Call to *<new_target>.dnd_enter(source, event)*

3. Call to *<target>.dnd_commit(source, event)* to notify of drop
4. Call to *<source>.dnd_end(target, event)* to signal end of drag-and-drop

class tkinter.dnd.DndHandler(*source*, *event*)

The *DndHandler* class handles drag-and-drop events tracking Motion and ButtonRelease events on the root of the event widget.

cancel(*event=None*)

Cancel the drag-and-drop process.

finish(*event*, *commit=0*)

Execute end of drag-and-drop functions.

on_motion(*event*)

Inspect area below mouse for target objects while drag is performed.

on_release(*event*)

Signal end of drag when the release pattern is triggered.

tkinter.dnd.dnd_start(*source*, *event*)

Factory function for drag-and-drop process.

Bindings and Events

`tkinter.ttk` — Tk themed widgets

Source code: Lib/tkinter/ttk.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/ttk.py]

The `tkinter.ttk` module provides access to the Tk themed widget set, introduced in Tk 8.5. It provides additional benefits including anti-aliased font rendering under X11 and window transparency (requiring a composition window manager on X11).

The basic idea for `tkinter.ttk` is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

Tk Widget Styling Support [https://core.tcl.tk/tips/doc/trunk/tip/48.md]
A document introducing theming support for Tk

Using Ttk

To start using Ttk, import its module:

```
from tkinter import ttk
```

To override the basic Tk widgets, the import should follow the Tk import:

```
from tkinter import *
from tkinter.ttk import *
```

That code causes several `tkinter.ttk` widgets (**`Button`**,

Checkbutton, **Entry**, **Frame**, **Label**, **LabelFrame**, **Menubutton**, **PanedWindow**, **Radiobutton**, **Scale** and **Scrollbar**) to automatically replace the Tk widgets.

This has the direct benefit of using the new widgets which gives a better look and feel across platforms; however, the replacement widgets are not completely compatible. The main difference is that widget options such as “fg”, “bg” and others related to widget styling are no longer present in Ttk widgets. Instead, use the **ttk.Style** class for improved styling effects.

See also

Converting existing applications to use Tile widgets **[https://tktable.sourceforge.net/tile/doc/converting.txt]**
: A monograph (using Tcl terminology) about differences typically encountered when moving applications to use the new widgets.

Ttk Widgets

Ttk comes with 18 widgets, twelve of which already existed in tkinter: **Button**, **Checkbutton**, **Entry**, **Frame**, **Label**, **LabelFrame**, **Menubutton**, **PanedWindow**, **Radiobutton**, **Scale**, **Scrollbar**, and **Spinbox**. The other six are new: **Combobox**, **Notebook**, **Progressbar**, **Separator**, **Sizegrip** and **Treeview**. And all them are subclasses of **Widget**.

Using the Ttk widgets gives the application an improved look and feel. As discussed above, there are differences in how the styling is coded.

Tk code:

```
l1 = tkinter.Label(text="Test", fg="black", bg="white")
l2 = tkinter.Label(text="Test", fg="black", bg="white")
```

Ttk code:

```
style = ttk.Style()
```

```
style.configure("BW.TLabel", foreground="black", backgro

l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about TtkStyling, see the **`Style`** class documentation.

Widget

`ttk.Widget` defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

Standard Options

All the **`ttk`** Widgets accepts the following options:

Option	Description
class	Specifies the window class. The class is used when querying the option database for the window's other options, to determine the default bindtags for the window, and to select the widget's default layout and style. This option is read-only, and may only be specified when the window is created.
cursor	Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited for the parent widget.
takefocus	Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0 is returned, it means that the window should be skipped entirely during keyboard traversal. If 1, it means that the window should receive the input focus as long as it is viewable. And an empty string means that the traversal scripts make the decision about whether or not to focus on the window.
style	May be used to specify a custom widget style.

Scrollable Widget Options

The following options are supported by widgets that are controlled by a scrollbar.

Option	Description
xscrollcommand	Used to communicate with horizontal scrollbars. When the view in the widget's window change, the widget will generate a Tcl command based on the scrollcommand. Usually this option consists of the method `Scrollbar.set()` of some scrollbar. This will cause the scrollbar to be updated whenever the view in the window changes.
yscrollcommand	Used to communicate with vertical scrollbars. For some more information, see above.

Label Options

The following options are supported by labels, buttons and other button-like widgets.

Option	Description
text	Specifies a text string to be displayed inside the widget.
textvariable	Specifies a name whose value will be used in place of the text option resource.
underline	If set, specifies the index (0-based) of a character to underline in the text string. The underline character is used for mnemonic activation.
image	Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list if a sequence of statespec/value pairs as defined by `Style.map()`, specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same size.
compound	Specifies how to display the image relative to the text, in the case both text and images options are

present. Valid values are:

- text: display text only
- image: display image only
- top, bottom, left, right: display image above, below, left of, or right of the text, respectively.
- none: the default. display the image if present, otherwise the text.

width: If greater than zero, specifies how much space, in character widths, to allocate for the text label, if less than zero, specifies a minimum width. If zero or unspecified, the natural width of the text label is used.

Compatibility Options

Option	Description
state	May be set to “normal” or “disabled” to control the “disabled” state bit. This is a write-only option: setting it changes the widget state, but the `Widget.state()` method does not affect this option.

Widget States

The widget state is a bitmap of independent state flags.

Flag	Description
active	The mouse cursor is over the widget and pressing a mouse button will cause some action to occur
disabled	Widget is disabled under program control
focus	Widget has keyboard focus
pressed	Widget is being pressed
selected	“On”, “true”, or “current” for things like Checkbuttons and radiobuttons
background	Windows and Mac have a notion of an “active” or foreground window. The *background* state is set for widgets in a background window, and cleared for those in the foreground window

readonly	Widget should not allow user modification
alternate	A widget-specific alternate display format
invalid	The widget's value is invalid

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

ttk.Widget

Besides the methods described below, the **`ttk.Widget`** supports the methods **`tkinter.Widget.cget()`** and **`tkinter.Widget.configure()`**.

class tkinter.ttk.Widget

identify(*x*, *y*)

Returns the name of the element at position *x y*, or the empty string if the point does not lie within any element.

x and *y* are pixel coordinates relative to the widget.

instate(*statespec*, *callback=None*, **args*, ***kw*)

Test the widget's state. If a callback is not specified, returns `True` if the widget state matches *statespec* and `False` otherwise. If callback is specified then it is called with args if widget state matches *statespec*.

state(*statespec=None*)

Modify or inquire widget state. If *statespec* is specified, sets the widget state according to it and return a new *statespec* indicating which flags were changed. If *statespec* is not specified, returns the currently enabled state flags.

statespec will usually be a list or a tuple.

Combobox

The **ttk.Combobox** widget combines a text field with a pop-down list of values. This widget is a subclass of **Entry**.

Besides the methods inherited from **Widget**: **Widget.cget()**, **Widget.configure()**, **Widget.identify()**, **Widget.instate()** and **Widget.state()**, and the following inherited from **Entry**: **Entry.bbox()**, **Entry.delete()**, **Entry.icursor()**, **Entry.index()**, **Entry.insert()**, **Entry.selection()**, **Entry.xview()**, it has some other methods, described at **ttk.Combobox**.

Options

This widget accepts the following specific options:

Option	Description
exportselection	If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking Misc.selection_get, for example).
justify	Specifies how the text is aligned within the widget. One of “left”, “center”, or “right”.
height	Specifies the height of the pop-down listbox, in rows.
postcommand	A script (possibly registered with Misc.register) that is called immediately before displaying the values. It may specify which values to display.
state	One of “normal”, “readonly”, or “disabled”. In the “readonly” state, the value may not be edited directly, and the user can only selection of the values from the dropdown list. In the “normal” state, the text field is directly editable. In the “disabled” state, no interaction is possible.
textvariable	Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See **tkinter.StringVar**.
values	Specifies the list of values to display in the drop-down listbox.

width Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget's font.

Virtual events

The combobox widgets generates a <<**ComboboxSelected**>> virtual event when the user selects an element from the list of values.

ttk.Combobox

class tkinter.ttk.Combobox

current(*newindex=None*)

If *newindex* is specified, sets the combobox value to the element position *newindex*. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

get()

Returns the current value of the combobox.

set(*value*)

Sets the value of the combobox to *value*.

Spinbox

The **ttk.Spinbox** widget is a **ttk.Entry** enhanced with increment and decrement arrows. It can be used for numbers or lists of string values. This widget is a subclass of **Entry**.

Besides the methods inherited from **Widget**: **Widget.cget()**, **Widget.configure()**, **Widget.identify()**, **Widget.instate()** and **Widget.state()**, and the following inherited from **Entry**: **Entry.bbox()**, **Entry.delete()**, **Entry.icursor()**, **Entry.index()**, **Entry.insert()**, **Entry.xview()**, it has some other methods, described at

ttk.Spinbox.

Options

This widget accepts the following specific options:

Option	Description
from	Float value. If set, this is the minimum value to which the decrement button will decrement. Must be spelled as `from_` when used as an argument, since `from` is a Python keyword.
to	Float value. If set, this is the maximum value to which the increment button will increment.
increment	Float value. Specifies the amount which the increment/decrement buttons change the value. Defaults to 1.0.
values	Sequence of string or float values. If specified, the increment/decrement buttons will cycle through the items in this sequence rather than incrementing or decrementing numbers.
wrap	Boolean value. If `True`, increment and decrement buttons will cycle from the `to` value to the `from` value or the `from` value to the `to` value, respectively.
format	String value. This specifies the format of numbers set by the increment/decrement buttons. It must be in the form "%W.Pf", where W is the padded width of the value, P is the precision, and '%' and 'f' are literal.
command	Python callable. Will be called with no arguments whenever either of the increment or decrement buttons are pressed.

Virtual events

The spinbox widget generates an <<**Increment**>> virtual event when the user presses <Up>, and a <<**Decrement**>> virtual event when the user presses <Down>.

ttk.Spinbox

class tkinter.ttk.Spinbox

get()

Returns the current value of the spinbox.

set(*value*)

Sets the value of the spinbox to *value*.

Notebook

Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently displayed window.

Options

This widget accepts the following specific options:

Option	Description
height	If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.
padding	Specifies the amount of extra space to add around the outside of the notebook. The padding is a list up to four length specifications left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.
width	If present and greater than zero, specified the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.

Tab Options

There are also specific options for tabs:

Option	Description
state	Either “normal”, “disabled” or “hidden”. If “disabled”, then the tab is not selectable. If “hidden”, then the tab is not shown.
sticky	Specifies how the child window is positioned

	within the pane area. Value is a string containing zero or more of the characters “n”, “s”, “e” or “w”. Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the `grid()` geometry manager.
padding	Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.
text	Specifies a text to be displayed in the tab.
image	Specifies an image to display in the tab. See the option image described in `Widget`.
compound	Specifies how to display the image relative to the text, in the case both options text and image are present. See Label Options for legal values.
underline	Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if `Notebook.enable_traversal()` is called.

Tab Identifiers

The tab_id present in several methods of `ttk.Notebook` may take any of the following forms:

- An integer between zero and the number of tabs
- The name of a child window
- A positional specification of the form “@x,y”, which identifies the tab
- The literal string “current”, which identifies the currently selected tab
- The literal string “end”, which returns the number of tabs (only valid for `Notebook.index()`)

Virtual Events

This widget generates a <<**NotebookTabChanged**>> virtual event after a new tab is selected.

ttk.Notebook

class tkinter.ttk.Notebook

add(*child*, ***kw*)

Adds a new tab to the notebook.

If window is currently managed by the notebook but hidden, it is restored to its previous position.

See Tab Options for the list of available options.

forget(*tab_id*)

Removes the tab specified by *tab_id*, unmaps and unmanages the associated window.

hide(*tab_id*)

Hides the tab specified by *tab_id*.

The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the `add()` command.

identify(*x*, *y*)

Returns the name of the tab element at position *x*, *y*, or the empty string if none.

index(*tab_id*)

Returns the numeric index of the tab specified by *tab_id*, or the total number of tabs if *tab_id* is the string “end”.

insert(*pos*, *child*, ***kw*)

Inserts a pane at the specified position.

pos is either the string “end”, an integer index, or the name of a managed child. If *child* is already managed by the notebook, moves it to the specified position.

See Tab Options for the list of available options.

select(*tab_id=None*)

Selects the specified *tab_id*.

The associated child window will be displayed, and the previously selected window (if different) is unmapped. If *tab_id* is omitted, returns the widget name of the currently selected pane.

tab(*tab_id*, *option=None*, ***kw*)

Query or modify the options of the specific *tab_id*.

If *kw* is not given, returns a dictionary of the tab option values. If *option* is specified, returns the value of that *option*. Otherwise, sets the options to the corresponding values.

tabs()

Returns a list of windows managed by the notebook.

enable_traversal()

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows:

- `Control-Tab`: selects the tab following the currently selected one.
- `Shift-Control-Tab`: selects the tab preceding the currently selected one.
- `Alt-K`: where *K* is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.

Progressbar

The **`ttk.Progressbar`** widget shows the status of a long-running operation. It can operate in two modes: 1) the determinate mode which shows the amount completed relative to the total amount of work to be done and 2) the indeterminate mode which provides an animated display to let the user know that work is progressing.

Options

This widget accepts the following specific options:

Option	Description
orient	One of “horizontal” or “vertical”. Specifies the orientation of the progress bar.
length	Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).
mode	One of “determinate” or “indeterminate”.
maximum	A number specifying the maximum value. Defaults to 100.
value	The current value of the progress bar. In “determinate” mode, this represents the amount of work completed. In “indeterminate” mode, it is interpreted as modulo *maximum*; that is, the progress bar completes one “cycle” when its value increases by *maximum*.
variable	A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.
phase	Read-only option. The widget periodically increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the current theme to provide additional animation effects.

ttk.Progressbar

class tkinter.ttk.Progressbar

start(*interval* = *None*)

Begin autoincrement mode: schedules a recurring timer event that calls `Progressbar.step()` every *interval* milliseconds. If omitted, *interval* defaults to 50 milliseconds.

step(*amount* = *None*)

Increments the progress bar's value by *amount*.

amount defaults to 1.0 if omitted.

stop()

Stop autoincrement mode: cancels any recurring timer event initiated by `Progressbar.start()` for this progress bar.

Separator

The `ttk.Separator` widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from `ttk.Widget`.

Options

This widget accepts the following specific option:

Option	Description
orient	One of "horizontal" or "vertical". Specifies the orientation of the separator.

Sizegrip

The `ttk.Sizegrip` widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and

dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from **`ttk.Widget`**.

Platform-specific notes

- On macOS, toplevel windows automatically include a built-in size grip by default. Adding a **`Sizegrip`** is harmless, since the built-in grip will just mask the widget.

Bugs

- If the containing toplevel's position was specified relative to the right or bottom of the screen (e.g. ….), the **`Sizegrip`** widget will not resize the window.
- This widget supports only "southeast" resizing.

Treeview

The **`ttk.Treeview`** widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option `displaycolumns`. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option columns. See Column Identifiers.

Each item is identified by a unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named `{}`. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in Scrollable Widget Options and the methods `Treeview.xview()` and `Treeview.yview()`.

Options

This widget accepts the following specific options:

Option	Description
columns	A list of column identifiers, specifying the number of columns and their names.
displaycolumns	A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string “#all”.
height	Specifies the number of rows which should be visible. Note: the requested width is determined from the sum of the column widths.
padding	Specifies the internal padding for the widget. The padding is a list of up to four length specifications.
selectmode	Controls how the built-in class bindings manage the selection. One of “extended”, “browse” or “none”. If set to “extended” (the default), multiple items may be selected. If “browse”, only a single item will be selected at a time. If “none”, the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.
show	A list containing zero or more of the following values, specifying which elements of the tree to display. • tree: display tree labels in column #0. • headings: display the heading row. The default is “tree headings”, i.e., show all elements. **Note**: Column #0 always refers to the tree column, even if show = ”tree” is not specified.

Item Options

The following item options may be specified for items in the insert and item widget commands.

Option	Description
`-text`	Text textual label to display for the item.
`-image`	An Tk image, displayed to the left of the label.
`-values`	The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.
`-open`	Open/`False` value indicating whether the item's children should be displayed or hidden.
`-tags`	A list of tags associated with this item.

Tag Options

The following options may be specified on tags:

Option	Description
`-foreground`	Specifies the text foreground color.
`-background`	Specifies the cell or item background color.
`-font`	Specifies the font to use when drawing text.
`-image`	Specifies the item image, in case the item's image option is empty.

Column Identifiers

Column identifiers take any of the following forms:

- A symbolic name from the list of columns option.
- An integer n, specifying the nth data column.
- A string of the form #n, where n is an integer, specifying the nth display column.

Notes:

- Item's option values may be displayed in a different order than the order in which they are stored.
- Column #0 always refers to the tree column, even if show = "tree" is not specified.

A data column number is an index into an item's option values list; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column #0. If option displaycolumns is not set, then data column n is displayed in column #n + 1. Again, **column #0 always refers to the tree column**.

Virtual Events

The Treeview widget generates the following virtual events.

Event	Description
<<TreeviewSelect>>	Generated whenever the selection changes.
<<TreeviewOpen>>	Generated just before settings the focus item to open = True.
<<TreeviewClose>>	Generated just after setting the focus item to open = False.

The `Treeview.focus()` and `Treeview.selection()` methods can be used to determine the affected item or items.

ttk.Treeview

class tkinter.ttk.Treeview

bbox(*item*, *column* = *None*)

Returns the bounding box (relative to the treeview widget's window) of the specified *item* in the form (x, y, width, height).

If *column* is specified, returns the bounding box of that cell. If the *item* is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

get_children(*item=None*)

Returns the list of children belonging to *item*.

If *item* is not specified, returns root children.

set_children(*item*, **newchildren*)

Replaces *item*'s child with *newchildren*.

Children present in *item* that are not present in *newchildren* are detached from the tree. No items in *newchildren* may be an ancestor of *item*. Note that not specifying *newchildren* results in detaching *item*'s children.

column(*column*, *option=None*, ***kw*)

Query or modify the options for the specified *column*.

If *kw* is not given, returns a dict of the column option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- id
  Returns the column name. This is a read-only option.

- anchor: One of the standard Tk anchor values.
  Specifies how the text in this column should be aligned with respect to the cell.

- minwidth: width
  The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.

- stretch: `True/False`
  Specifies whether the column's width should be adjusted when the widget is resized.

- width: width
  The width of the column in pixels.

To configure the tree column, call this with column = "#0"

delete(**items*)

Delete all specified *items* and all their descendants.

The root item may not be deleted.

detach(**items*)

Unlinks all of the specified *items* from the tree.

The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.

The root item may not be detached.

exists(*item*)

Returns `True` if the specified *item* is present in the tree.

focus(*item=None*)

If *item* is specified, sets the focus item to *item*. Otherwise, returns the current focus item, or '' if there is none.

heading(*column*, *option=None*, ***kw*)

Query or modify the heading options for the specified *column*.

If *kw* is not given, returns a dict of the heading option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- text: text
  The text to display in the column heading.

- image: imageName
  Specifies an image to display to the right of the column heading.

- anchor: anchor
  Specifies how the heading text should be aligned. One of the standard Tk anchor values.

- command: callback
  A callback to be invoked when the heading label is pressed.

To configure the tree column heading, call this with column = "#0".

identify(*component*, *x*, *y*)

Returns a description of the specified *component* under the point given by *x* and *y*, or the empty string if no such *component* is present at that position.

identify_row(*y*)

Returns the item ID of the item at position *y*.

identify_column(*x*)

Returns the data column identifier of the cell at position *x*.

The tree column has ID #0.

identify_region(*x*, *y*)

Returns one of:

region	
heading	Tree heading area.
separator	Space between two columns headings.
tree	The tree area.
cell	A data cell.

Availability: Tk 8.6.

identify_element(*x*, *y*)

Returns the element at position *x*, *y*.

Availability: Tk 8.6.

index(*item*)

Returns the integer index of *item* within its parent's list of children.

insert(*parent*, *index*, *iid*=*None*, ***kw*)

Creates a new item and returns the item identifier of the newly created item.

parent is the item ID of the parent item, or the empty string to create a new top-level item. *index* is an integer, or the value "end", specifying where in the list of parent's children to insert the new item. If *index* is less than or equal to zero, the new node is inserted at the beginning; if *index* is greater than or equal to the current number of children, it is inserted at the end. If *iid* is specified, it is used as the item identifier; *iid* must not already exist in the tree. Otherwise, a new unique identifier is generated.

See Item Options for the list of available points.

item(*item*, *option*=*None*, ****kw*)

Query or modify the options for the specified *item*.

If no options are given, a dict with options/values for the item is returned. If *option* is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values as given by *kw*.

move(*item*, *parent*, *index*)

Moves *item* to position *index* in *parent*'s list of children.

It is illegal to move an item under one of its descendants. If *index* is less than or equal to zero, *item* is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If *item* was detached it is reattached.

next(*item*)

Returns the identifier of *item*'s next sibling, or '' if *item* is the last child of its parent.

parent(*item*)

Returns the ID of the parent of *item*, or '' if *item* is at the top level of the hierarchy.

prev(*item*)

Returns the identifier of *item*'s previous sibling, or '' if *item* is the first child of its parent.

reattach(*item*, *parent*, *index*)

An alias for **`Treeview.move()`**.

see(*item*)

Ensure that *item* is visible.

Sets all of *item*'s ancestors open option to `True`, and scrolls the widget if necessary so that *item* is within the

visible portion of the tree.

selection()

Returns a tuple of selected items.

Changed in version 3.8: `selection()` no longer takes arguments. For changing the selection state use the following selection methods.

selection_set(**items*)

items becomes the new selection.

Changed in version 3.6: items can be passed as separate arguments, not just as a single tuple.

selection_add(**items*)

Add *items* to the selection.

Changed in version 3.6: items can be passed as separate arguments, not just as a single tuple.

selection_remove(**items*)

Remove *items* from the selection.

Changed in version 3.6: items can be passed as separate arguments, not just as a single tuple.

selection_toggle(**items*)

Toggle the selection state of each item in *items*.

Changed in version 3.6: items can be passed as separate arguments, not just as a single tuple.

set(*item*, *column=None*, *value=None*)

With one argument, returns a dictionary of column/value pairs for the specified *item*. With two arguments, returns the current value of the specified *column*. With

three arguments, sets the value of given *column* in given *item* to the specified *value*.

tag_bind(*tagname*, *sequence*=*None*, *callback*=*None*)

Bind a callback for the given event *sequence* to the tag *tagname*. When an event is delivered to an item, the callbacks for each of the item's tags option are called.

tag_configure(*tagname*, *option*=*None*, ***kw*)

Query or modify the options for the specified *tagname*.

If *kw* is not given, returns a dict of the option settings for *tagname*. If *option* is specified, returns the value for that *option* for the specified *tagname*. Otherwise, sets the options to the corresponding values for the given *tagname*.

tag_has(*tagname*, *item*=*None*)

If *item* is specified, returns 1 or 0 depending on whether the specified *item* has the given *tagname*. Otherwise, returns a list of all items that have the specified tag.

Availability: Tk 8.6

xview(**args*)

Query or modify horizontal position of the treeview.

yview(**args*)

Query or modify vertical position of the treeview.

Ttk Styling

Each widget in **ttk** is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If you don't know the class

name of a widget, use the method **`Misc.winfo_class()`** (somewidget.winfo_class()).

Tcl'2004 conference presentation **[https://tktable.sourceforge.net/tile/tile-tcl2004.pdf]**
This document explains how the theme engine works

class tkinter.ttk.Style
This class is used to manipulate the style database.

configure(*style*, *query_opt=None*, ***kw*)
Query or set the default value of the specified option(s) in *style*.

Each key in *kw* is an option and each value is a string identifying the value for that option.

For example, to change every default button to be a flat button with some padding and a different background color:

```
from tkinter import ttk
import tkinter

root = tkinter.Tk()

ttk.Style().configure("TButton", padding=6, rel
   background="#ccc")

btn = ttk.Button(text="Sample")
btn.pack()

root.mainloop()
```

map(*style*, *query_opt=None*, ***kw*)
Query or sets dynamic values of the specified option(s) in *style*.

Each key in *kw* is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or some other preference. A statespec is a compound of one or more states and then a value.

An example may make it more understandable:

```
import tkinter
from tkinter import ttk

root = tkinter.Tk()

style = ttk.Style()
style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active',
    background=[('pressed', '!disabled', 'black
    )

colored_btn = ttk.Button(text="Test", style="C.

root.mainloop()
```

Note that the order of the (states, value) sequences for an option does matter, if the order is changed to `[('active', 'blue'), ('pressed', 'red')]` in the foreground option, for example, the result would be a blue foreground when the widget were in active or pressed states.

lookup(*style*, *option*, *state*=*None*, *default*=*None*)

Returns the value specified for *option* in *style*.

If *state* is specified, it is expected to be a sequence of one or more states. If the *default* argument is set, it is used as a fallback value in case no specification for option is found.

To check what font a Button uses by default:

```
from tkinter import ttk
```

```
print(ttk.Style().lookup("TButton", "font"))
```

layout(*style*, *layoutspec=None*)

Define the widget layout for given *style*. If *layoutspec* is omitted, return the layout specification for given style.

layoutspec, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in Layouts.

To understand the format, see the following example (it is not intended to do anything useful):

```
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.layout("TMenubutton", [
    ("Menubutton.background", None),
    ("Menubutton.button", {"children":
        [("Menubutton.focus", {"children":
            [("Menubutton.padding", {"children":
                [("Menubutton.label", {"side": '
            })]
        })]
    }),
])

mbtn = ttk.Menubutton(text='Text')
mbtn.pack()
root.mainloop()
```

element_create(*elementname*, *etype*, **args*, ***kw*)

Create a new element in the current theme, of the given *etype* which is expected to be either “image”, “from” or “vsapi”. The latter is only available in Tk 8.6a for Windows XP and Vista and is not described here.

If “image” is used, *args* should contain the default image name followed by statespec/value pairs (this is the imagespec), and *kw* may have the following options:

- border = padding
  padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.

- height = height
  Specifies a minimum height for the element. If less than zero, the base image’s height is used as a default.

- padding = padding
  Specifies the element’s interior padding. Defaults to border’s value if not specified.

- sticky = spec
  Specifies how the image is placed within the final parcel. spec contains zero or more characters “n”, “s”, “w”, or “e”.

- width = width
  Specifies a minimum width for the element. If less than

zero, the base image's width is used as a default.

If "from" is used as the value of *etype*, `element_create()` will clone an existing element. *args* is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. *kw* is discarded.

element_names()

Returns the list of elements defined in the current theme.

element_options(*elementname*)

Returns the list of *elementname*'s options.

theme_create(*themename*, *parent*=*None*, *settings*=*None*)

Create a new theme.

It is an error if *themename* already exists. If *parent* is specified, the new theme will inherit styles, elements and layouts from the parent theme. If *settings* are present they are expected to have the same syntax used for `theme_settings()`.

theme_settings(*themename*, *settings*)

Temporarily sets the current theme to *themename*, apply specified *settings* and then restore the previous theme.

Each key in *settings* is a style and each value may contain the keys 'configure', 'map', 'layout' and 'element create' and they are expected to have the same format as specified by the methods `Style.configure()`, `Style.map()`, `Style.layout()` and `Style.element_create()` respectively.

As an example, let's change the Combobox for the default theme a bit:

```
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
   "TCombobox": {
       "configure": {"padding": 5},
       "map": {
           "background": [("active", "green2"),
                          ("!disabled", "green4
           "fieldbackground": [("!disabled", "g
           "foreground": [("focus", "OliveDrab1
                          ("!disabled", "OliveD
       }
   }
})

combo = ttk.Combobox().pack()

root.mainloop()
```

theme_names()

Returns a list of all known themes.

theme_use(*themename*=*None*)

If *themename* is not given, returns the theme in use. Otherwise, sets the current theme to *themename*, refreshes all widgets and emits a <<ThemeChanged>> event.

Layouts

A layout can be just `None`, if it takes no options, or a dict of

options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager: given an initial cavity, each element is allocated a parcel. Valid options/values are:

- side: whichside
  Specifies which side of the cavity to place the element; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.

- sticky: nswe
  Specifies where the element is placed inside its allocated parcel.

- unit: 0 or 1
  If set to 1, causes the element and all of its descendants to be treated as a single element for the purposes of `Widget.identify()` et al. It's used for things like scrollbar thumbs with grips.

- children: [sublayout…]
  Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a Layout.

`tkinter.tix` — Extension widgets for Tk

Source code: Lib/tkinter/tix.py [https://github.com/python/cpython/tree/3.11/Lib/tkinter/tix.py]

Deprecated since version 3.6: This Tk extension is unmaintained and should not be used in new code. Use `tkinter.ttk` instead.

The `tkinter.tix` (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The `tkinter.tix` library provides most of the commonly needed widgets that are missing from standard Tk: `HList`, `ComboBox`, `Control` (a.k.a. SpinBox) and an assortment of scrollable widgets. `tkinter.tix` also includes many more widgets that are generally useful in a wide range of applications: `NoteBook`, `FileEntry`, `PanedWindow`, etc; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

docs/tix-book/tix.book.html]
On-line version of the programmer's reference material.

Tix Development Applications [https://tix.sourceforge.net/Tixapps/src/Tide.html]
Tix applications for development of Tix and Tkinter programs. Tide applications work under Tk or Tkinter, and include **TixInspect**, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.

Using Tix

class tkinter.tix.Tk(*screenName=None*, *baseName=None*, *className='Tix'*)

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the **tkinter.tix** module subclasses the classes in the **tkinter**. The former imports the latter, so to use **tkinter.tix** with Tkinter, all you need to do is to import one module. In general, you can just import **tkinter.tix**, and replace the toplevel call to **tkinter.Tk** with **tix.Tk**:

```
from tkinter import tix
from tkinter.constants import *
root = tix.Tk()
```

To use **tkinter.tix**, you must have the Tix widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following:

```
from tkinter import tix
root = tix.Tk()
root.tk.eval('package require Tix')
```

Tix Widgets

Tix [https://tix.sourceforge.net/dist/current/man/html/TixCmd/TixIntro.htm]

introduces over 40 widget classes to the **tkinter** repertoire.

Basic Widgets

class tkinter.tix.Balloon

A Balloon [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixBalloon.htm] that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a Balloon widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

class tkinter.tix.ButtonBox

The ButtonBox [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixButtonBox.htm] widget creates a box of buttons, such as is commonly used for `Ok Cancel`.

class tkinter.tix.ComboBox

The ComboBox [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixComboBox.htm] widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

class tkinter.tix.Control

The Control [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixControl.htm] widget is also known as the **SpinBox** widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

class tkinter.tix.LabelEntry

The LabelEntry [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixLabelEntry.htm] widget packages an entry widget and a label into one mega widget. It can be used to simplify the creation of “entry-form” type of interface.

class tkinter.tix.LabelFrame

The LabelFrame [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixLabelFrame.htm] widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the **`frame`** subwidget and manage them inside the **`frame`** subwidget.

class tkinter.tix.Meter

The Meter [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixMeter.htm] widget can be used to show the progress of a background job which may take a long time to execute.

class tkinter.tix.OptionMenu

The OptionMenu [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixOptionMenu.htm] creates a menu button of options.

class tkinter.tix.PopupMenu

The PopupMenu [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixPopupMenu.htm] widget can be used as a replacement of the `tk_popup` command. The advantage of the **`Tix PopupMenu`** widget is it requires less application code to manipulate.

class tkinter.tix.Select

The Select [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixSelect.htm] widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

class tkinter.tix.StdButtonBox

The StdButtonBox [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixStdButtonBox.htm] widget is a group of standard buttons for Motif-like dialog boxes.

File Selectors

class tkinter.tix.DirList

The DirList [https://tix.sourceforge.net/dist/current/man/html/TixCmd/

tixDirList.htm] widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

class tkinter.tix.DirTree

The DirTree [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixDirTree.htm] widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

class tkinter.tix.DirSelectDialog

The DirSelectDialog [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixDirSelectDialog.htm] widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

class tkinter.tix.DirSelectBox

The **DirSelectBox** is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a ComboBox widget so that they can be quickly selected again.

class tkinter.tix.ExFileSelectBox

The ExFileSelectBox [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixExFileSelectBox.htm] widget is usually embedded in a tixExFileSelectDialog widget. It provides a convenient method for the user to select files. The style of the **ExFileSelectBox** widget is very similar to the standard file dialog on MS Windows 3.1.

class tkinter.tix.FileSelectBox

The FileSelectBox [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixFileSelectBox.htm] is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a

file. FileSelectBox stores the files mostly recently selected into a **ComboBox** widget so that they can be quickly selected again.

class tkinter.tix.FileEntry

The FileEntry [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixFileEntry.htm] widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the button widget that sits next to the entry, which will bring up a file selection dialog.

Hierarchical ListBox

class tkinter.tix.HList

The HList [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixHList.htm] widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

class tkinter.tix.CheckList

The CheckList [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixCheckList.htm] widget displays a list of items to be selected by the user. CheckList acts similarly to the Tk checkbutton or radiobutton widgets, except it is capable of handling many more items than checkbuttons or radiobuttons.

class tkinter.tix.Tree

The Tree [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixTree.htm] widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

Tabular ListBox

class tkinter.tix.TList

The TList [https://tix.sourceforge.net/dist/current/man/html/TixCmd/

tixTList.htm] widget can be used to display data in a tabular format. The list entries of a **TList** widget are similar to the entries in the Tk listbox widget. The main differences are (1) the **TList** widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.

Manager Widgets

class tkinter.tix.PanedWindow

The PanedWindow [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixPanedWindow.htm] widget allows the user to interactively manipulate the sizes of several panes. The panes can be arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

class tkinter.tix.ListNoteBook

The ListNoteBook [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixListNoteBook.htm] widget is very similar to the **TixNoteBook** widget: it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the **hlist** subwidget.

class tkinter.tix.NoteBook

The NoteBook [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixNoteBook.htm] widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual “tabs” at the top of the NoteBook widget.

Image Types

The **tkinter.tix** module adds:

- pixmap [https://tix.sourceforge.net/dist/current/man/html/TixCmd/pixmap.htm] capabilities to all **tkinter.tix** and **tkinter** widgets to create color images from XPM files.
- Compound [https://tix.sourceforge.net/dist/current/man/html/TixCmd/compound.htm] image types can be used to create images that consists of multiple horizontal lines; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk **Button** widget.

Miscellaneous Widgets

class tkinter.tix.InputOnly

The InputOnly [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixInputOnly.htm] widgets are to accept inputs from the user, which can be done with the `bind` command (Unix only).

Form Geometry Manager

In addition, **tkinter.tix** augments **tkinter** by providing:

class tkinter.tix.Form

The Form [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tixForm.htm] geometry manager based on attachment rules for all Tk widgets.

Tix Commands

class tkinter.tix.tixCommand

The tix commands [https://tix.sourceforge.net/dist/current/man/html/TixCmd/tix.htm] provide access to miscellaneous elements of **Tix**'s internal state and the **Tix** application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

To view the current settings, the common usage is:

```
from tkinter import tix
root = tix.Tk()
print(root.tix_configure())
```

tixCommand.tix_configure(*cnf=None*, ***kw*)

Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

tixCommand.tix_cget(*option*)

Returns the current value of the configuration option given by *option*. Option may be any of the configuration options.

tixCommand.tix_getbitmap(*name*)

Locates a bitmap file of the name `name.xpm` or `name` in one of the bitmap directories (see the **`tix_addbitmapdir()`** method). By using **`tix_getbitmap()`**, you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character `@`. The returned value can be used to configure the `bitmap` option of the Tk and Tix widgets.

tixCommand.tix_addbitmapdir(*directory*)

Tix maintains a list of directories under which the **`tix_getimage()`** and **`tix_getbitmap()`** methods will search for image files. The standard bitmap directory is `$TIX_LIBRARY/bitmaps`. The **`tix_addbitmapdir()`** method adds *directory* into this list. By using this method, the

image files of an applications can also be located using the **`tix_getimage()`** or **`tix_getbitmap()`** method.

tixCommand.tix_filedialog([*dlgclass*])

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to **`tix_filedialog()`**. An optional dlgclass parameter can be passed as a string to specified what type of file selection dialog widget is desired. Possible options are `tix`, `FileSelectDialog` or `tixExFileSelectDialog`.

tixCommand.tix_getimage(*self*, *name*)

Locates an image file of the name `name.xpm`, `name.xbm` or `name.ppm` in one of the bitmap directories (see the **`tix_addbitmapdir()`** method above). If more than one file with the same name (but different extensions) exist, then the image type is chosen according to the depth of the X display: xbm images are chosen on monochrome displays and color images are chosen on color displays. By using **`tix_getimage()`**, you can avoid hard coding the pathnames of the image files in your application. When successful, this method returns the name of the newly created image, which can be used to configure the `image` option of the Tk and Tix widgets.

tixCommand.tix_option_get(*name*)

Gets the options maintained by the Tix scheme mechanism.

tixCommand.tix_resetoptions(*newScheme*, *newFontSet*[, *newScmPrio*])

Resets the scheme and fontset of the Tix application to *newScheme* and *newFontSet*, respectively. This affects only those widgets created after this call. Therefore, it is best to call the resetoptions method before the creation of any widgets in a Tix application.

The optional parameter *newScmPrio* can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been has imported and inited, it is not possible to reset the color schemes and font sets using the **`tix_config()`** method. Instead, the **`tix_resetoptions()`** method must be used.

IDLE

Source code: Lib/idlelib/ [https://github.com/python/cpython/tree/3.11/Lib/idlelib/]

IDLE is Python's Integrated Development and Learning Environment.

IDLE has the following features:

- coded in 100% pure Python, using the **tkinter** GUI toolkit
- cross-platform: works mostly the same on Windows, Unix, and macOS
- Python shell window (interactive interpreter) with colorizing of code input, output, and error messages
- multi-window text editor with multiple undo, Python colorizing, smart indent, call tips, auto completion, and other features
- search within any window, replace within editor windows, and search through multiple files (grep)
- debugger with persistent breakpoints, stepping, and viewing of global and local namespaces
- configuration, browsers, and other dialogs

Menus

IDLE has two main window types, the Shell window and the Editor window. It is possible to have multiple editor windows simultaneously. On Windows and Linux, each has its own top menu. Each menu documented below indicates which window type it is associated with.

Output windows, such as used for Edit => Find in Files, are a subtype of editor window. They currently have the same top menu but a different default title and context menu.

On macOS, there is one application menu. It dynamically changes according to the window currently selected. It has an IDLE menu, and some entries described below are moved around to conform to Apple guidelines.

File menu (Shell and Editor)

New File
: Create a new file editing window.

Open…
: Open an existing file with an Open dialog.

Open Module…
: Open an existing module (searches sys.path).

Recent Files
: Open a list of recent files. Click one to open it.

Module Browser
: Show functions, classes, and methods in the current Editor file in a tree structure. In the shell, open a module first.

Path Browser
: Show sys.path directories, modules, functions, classes and methods in a tree structure.

Save
: Save the current window to the associated file, if there is one. Windows that have been changed since being opened or last saved have a * before and after the window title. If there is no associated file, do Save As instead.

Save As…
: Save the current window with a Save As dialog. The file saved becomes the new associated file for the window. (If your file namager is set to hide extensions, the current extension will be omitted in the file name box. If the new filename has no ‘.’, ‘.py’ and ‘.txt’ will be added for Python and text files, except that on macOS Aqua,’.py’ is added for all files.)

Save Copy As…
: Save the current window to different file without changing the associated file. (See Save As note above about filename extensions.)

Print Window
: Print the current window to the default printer.

Close Window
: Close the current window (if an unsaved editor, ask to save; if an unsaved Shell, ask to quit execution). Calling `exit()` or `close()` in the Shell window also closes Shell. If this is the only window, also exit IDLE.

Exit IDLE
: Close all windows and quit IDLE (ask to save unsaved edit windows).

Edit menu (Shell and Editor)

Undo
: Undo the last change to the current window. A maximum of 1000 changes may be undone.

Redo
: Redo the last undone change to the current window.

Select All
: Select the entire contents of the current window.

Cut
: Copy selection into the system-wide clipboard; then delete the selection.

Copy
: Copy selection into the system-wide clipboard.

Paste
: Insert contents of the system-wide clipboard into the current window.

The clipboard functions are also available in context menus.

Find…
: Open a search dialog with many options

Find Again
: Repeat the last search, if there is one.

Find Selection
: Search for the currently selected string, if there is one.

Find in Files…
: Open a file search dialog. Put results in a new output window.

Replace…
: Open a search-and-replace dialog.

Go to Line
: Move the cursor to the beginning of the line requested and make that line visible. A request past the end of the file goes to the end. Clear any selection and update the line and column status.

Show Completions
: Open a scrollable list allowing selection of existing names. See Completions in the Editing and navigation section below.

Expand Word
: Expand a prefix you have typed to match a full word in the same window; repeat to get a different expansion.

Show Call Tip
: After an unclosed parenthesis for a function, open a small window with function parameter hints. See Calltips in the Editing and navigation section below.

Show Surrounding Parens
: Highlight the surrounding parenthesis.

Format menu (Editor window only)

Format Paragraph
: Reformat the current blank-line-delimited paragraph in comment block or multiline string or selected line in a string. All lines in the paragraph will be formatted to less than N columns, where N defaults to 72.

Indent Region
: Shift selected lines right by the indent width (default 4 spaces).

Dedent Region
: Shift selected lines left by the indent width (default 4 spaces).

Comment Out Region
: Insert ## in front of selected lines.

Uncomment Region
: Remove leading # or ## from selected lines.

Tabify Region
: Turn *leading* stretches of spaces into tabs. (Note: We recommend using 4 space blocks to indent Python code.)

Untabify Region
: Turn *all* tabs into the correct number of spaces.

Toggle Tabs
: Open a dialog to switch between indenting with spaces and tabs.

New Indent Width
: Open a dialog to change indent width. The accepted default by the Python community is 4 spaces.

Strip Trailing Chitespace
: Remove trailing space and other whitespace characters after the last non-whitespace character of a line by applying str.rstrip to each line, including lines within multiline strings. Except for Shell windows, remove extra newlines at the end of the file.

Run menu (Editor window only)

Run Module
: Do Check Module. If no error, restart the shell to clean the environment, then execute the module. Output is displayed in the Shell window. Note that output requires use of `print` or `write`. When execution is complete, the Shell retains focus and displays a prompt. At this point, one may interactively explore the result of execution. This is similar to executing a file with `python -i file` at a command line.

Run… Customized
: Same as Run Module, but run the module with customized settings. *Command Line Arguments* extend **`sys.argv`** as if passed on a command line. The module can be run in the Shell without restarting.

Check Module
: Check the syntax of the module currently open in the Editor window. If the module has not been saved IDLE will either prompt the user to save or autosave, as selected in the General tab of the Idle Settings dialog. If there is a syntax error, the approximate location is indicated in the Editor window.

Python Shell
: Open or wake up the Python Shell window.

Shell menu (Shell window only)

View Last Restart
: Scroll the shell window to the last Shell restart.

Restart Shell
: Restart the shell to clean the environment and reset display and exception handling.

Previous History
: Cycle through earlier commands in history which match the

current entry.

Next History
: Cycle through later commands in history which match the current entry.

Interrupt Execution
: Stop a running program.

Debug menu (Shell window only)

Go to File/Line
: Look on the current line. with the cursor, and the line above for a filename and line number. If found, open the file if not already open, and show the line. Use this to view source lines referenced in an exception traceback and lines found by Find in Files. Also available in the context menu of the Shell window and Output windows.

Debugger (toggle)
: When activated, code entered in the Shell or run from an Editor will run under the debugger. In the Editor, breakpoints can be set with the context menu. This feature is still incomplete and somewhat experimental.

Stack Viewer
: Show the stack traceback of the last exception in a tree widget, with access to locals and globals.

Auto-open Stack Viewer
: Toggle automatically opening the stack viewer on an unhandled exception.

Options menu (Shell and Editor)

Configure IDLE
: Open a configuration dialog and change preferences for the following: fonts, indentation, keybindings, text color themes, startup windows and size, additional help sources, and extensions. On macOS, open the configuration dialog by

selecting Preferences in the application menu. For more details, see Setting preferences under Help and preferences.

Most configuration options apply to all windows or all future windows. The option items below only apply to the active window.

Show/Hide Code Context (Editor Window only)
: Open a pane at the top of the edit window which shows the block context of the code which has scrolled above the top of the window. See Code Context in the Editing and Navigation section below.

Show/Hide Line Numbers (Editor Window only)
: Open a column to the left of the edit window which shows the number of each line of text. The default is off, which may be changed in the preferences (see Setting preferences).

Zoom/Restore Height
: Toggles the window between normal size and maximum height. The initial size defaults to 40 lines by 80 chars unless changed on the General tab of the Configure IDLE dialog. The maximum height for a screen is determined by momentarily maximizing a window the first time one is zoomed on the screen. Changing screen settings may invalidate the saved height. This toggle has no effect when a window is maximized.

Window menu (Shell and Editor)

Lists the names of all open windows; select one to bring it to the foreground (deiconifying it if necessary).

Help menu (Shell and Editor)

About IDLE
: Display version, copyright, license, credits, and more.

IDLE Help
: Display this IDLE document, detailing the menu options, basic editing and navigation, and other tips.

Python Docs
: Access local Python documentation, if installed, or start a web browser and open docs.python.org showing the latest Python documentation.

Turtle Demo
: Run the turtledemo module with example Python code and turtle drawings.

Additional help sources may be added here with the Configure IDLE dialog under the General tab. See the Help sources subsection below for more on Help menu choices.

Context menus

Open a context menu by right-clicking in a window (Control-click on macOS). Context menus have the standard clipboard functions also on the Edit menu.

Cut
: Copy selection into the system-wide clipboard; then delete the selection.

Copy
: Copy selection into the system-wide clipboard.

Paste
: Insert contents of the system-wide clipboard into the current window.

Editor windows also have breakpoint functions. Lines with a breakpoint set are specially marked. Breakpoints only have an effect when running under the debugger. Breakpoints for a file are saved in the user's `.idlerc` directory.

Set Breakpoint
: Set a breakpoint on the current line.

Clear Breakpoint
: Clear the breakpoint on that line.

Shell and Output windows also have the following.

Go to file/line
: Same as in Debug menu.

The Shell window also has an output squeezing facility explained in the *Python Shell window* subsection below.

Squeeze
: If the cursor is over an output line, squeeze all the output between the code above and the prompt below down to a 'Squeezed text' label.

Editing and Navigation

Editor windows

IDLE may open editor windows when it starts, depending on settings and how you start IDLE. Thereafter, use the File menu. There can be only one open editor window for a given file.

The title bar contains the name of the file, the full path, and the version of Python and IDLE running the window. The status bar contains the line number ('Ln') and column number ('Col'). Line numbers start with 1; column numbers with 0.

IDLE assumes that files with a known .py* extension contain Python code and that other files do not. Run Python code with the Run menu.

Key bindings

In this section, 'C' refers to the `Control` key on Windows and Unix and the `Command` key on macOS.

- `Backspace` deletes to the left; `Del` deletes to the right
- `C-Backspace` delete word left; `C-Del` delete word to the right

- Arrow keys and `Page Up/Page Down` to move around
- `C-LeftArrow` and `C-RightArrow` moves by words
- `Home/End` go to begin/end of line
- `C-Home/C-End` go to begin/end of file
- Some useful Emacs bindings are inherited from Tcl/Tk:
    - `C-a` beginning of line
    - `C-e` end of line
    - `C-k` kill line (but doesn't put it in clipboard)
    - `C-l` center window around the insertion point
    - `C-b` go backward one character without deleting (usually you can also use the cursor key for this)
    - `C-f` go forward one character without deleting (usually you can also use the cursor key for this)
    - `C-p` go up one line (usually you can also use the cursor key for this)
    - `C-d` delete next character

Standard keybindings (like `C-c` to copy and `C-v` to paste) may work. Keybindings are selected in the Configure IDLE dialog.

Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, `Backspace` deletes up to 4 spaces if they are there. `Tab` inserts spaces (in the Python Shell window one tab), number depends on Indent width. Currently, tabs are restricted to four spaces due to Tcl/Tk limitations.

See also the indent/dedent region commands on the Format menu.

Search and Replace

Any selection becomes a search target. However, only selections within a line work because searches are only performed within lines with the terminal newline removed. If `[x] Regular expresion` is checked, the target is interpreted according to the Python re module.

Completions

Completions are supplied, when requested and available, for module names, attributes of classes or functions, or filenames. Each request method displays a completion box with existing names. (See tab completions below for an exception.) For any box, change the name being completed and the item highlighted in the box by typing and deleting characters; by hitting `Up`, `Down`, `PageUp`, `PageDown`, `Home`, and `End` keys; and by a single click within the box. Close the box with `Escape`, `Enter`, and double `Tab` keys or clicks outside the box. A double click within the box selects and closes.

One way to open a box is to type a key character and wait for a predefined interval. This defaults to 2 seconds; customize it in the settings dialog. (To prevent auto popups, set the delay to a large number of milliseconds, such as 100000000.) For imported module names or class or function attributes, type '.'. For filenames in the root directory, type **`os.sep`** or **`os.altsep`** immediately after an opening quote. (On Windows, one can specify a drive first.) Move into subdirectories by typing a directory name and a separator.

Instead of waiting, or after a box is closed, open a completion box immediately with Show Completions on the Edit menu. The default hot key is `C-space`. If one types a prefix for the desired name before opening the box, the first match or near miss is made visible. The result is the same as if one enters a prefix after the box is displayed. Show Completions after a quote completes filenames in the current directory instead of a root directory.

Hitting `Tab` after a prefix usually has the same effect as Show Completions. (With no prefix, it indents.) However, if there is only

one match to the prefix, that match is immediately added to the editor text without opening a box.

Invoking 'Show Completions', or hitting `Tab` after a prefix, outside of a string and without a preceding '.' opens a box with keywords, builtin names, and available module-level names.

When editing code in an editor (as oppose to Shell), increase the available module-level names by running your code and not restarting the Shell thereafter. This is especially useful after adding imports at the top of a file. This also increases possible attribute completions.

Completion boxes initially exclude names beginning with '_' or, for modules, not included in '__all__'. The hidden names can be accessed by typing '_' after '.', either before or after the box is opened.

Calltips

A calltip is shown automatically when one types `(` after the name of an *accessible* function. A function name expression may include dots and subscripts. A calltip remains until it is clicked, the cursor is moved out of the argument area, or `)` is typed. Whenever the cursor is in the argument part of a definition, select Edit and "Show Call Tip" on the menu or enter its shortcut to display a calltip.

The calltip consists of the function's signature and docstring up to the latter's first blank line or the fifth non-blank line. (Some builtin functions lack an accessible signature.) A '/' or '*' in the signature indicates that the preceding or following arguments are passed by position or name (keyword) only. Details are subject to change.

In Shell, the accessible functions depends on what modules have been imported into the user process, including those imported by Idle itself, and which definitions have been run, all since the last restart.

For example, restart the Shell and enter `itertools.count(`. A calltip appears because Idle imports itertools into the user process for its own use. (This could change.) Enter `turtle.write(` and nothing appears. Idle does not itself import turtle. The menu entry

and shortcut also do nothing. Enter `import turtle`. Thereafter, `turtle.write(` will display a calltip.

In an editor, import statements have no effect until one runs the file. One might want to run a file after writing import statements, after adding function definitions, or after opening an existing file.

Code Context

Within an editor window containing Python code, code context can be toggled in order to show or hide a pane at the top of the window. When shown, this pane freezes the opening lines for block code, such as those beginning with `class`, `def`, or `if` keywords, that would have otherwise scrolled out of view. The size of the pane will be expanded and contracted as needed to show the all current levels of context, up to the maximum number of lines defined in the Configure IDLE dialog (which defaults to 15). If there are no current context lines and the feature is toggled on, a single blank line will display. Clicking on a line in the context pane will move that line to the top of the editor.

The text and background colors for the context pane can be configured under the Highlights tab in the Configure IDLE dialog.

Shell window

In IDLE's Shell, enter, edit, and recall complete statements. (Most consoles and terminals only work with a single physical line at a time).

Submit a single-line statement for execution by hitting `Return` with the cursor anywhere on the line. If a line is extended with Backslash (`\`), the cursor must be on the last physical line. Submit a multi-line compound statement by entering a blank line after the statement.

When one pastes code into Shell, it is not compiled and possibly executed until one hits `Return`, as specified above. One may edit pasted code first. If one pastes more than one statement into Shell, the result will be a **`SyntaxError`** when multiple statements are

compiled as if they were one.

Lines containing `RESTART` mean that the user execution process has been re-started. This occurs when the user execution process has crashed, when one requests a restart on the Shell menu, or when one runs code in an editor window.

The editing features described in previous subsections work when entering code interactively. IDLE's Shell window also responds to the following keys.

- `C-c` interrupts executing command
- `C-d` sends end-of-file; closes window if typed at a `>>>` prompt
- `Alt-/` (Expand word) is also useful to reduce typing

  Command history

  - `Alt-p` retrieves previous command matching what you have typed. On macOS use `C-p`.
  - `Alt-n` retrieves next. On macOS use `C-n`.
  - `Return` while the cursor is on any previous command retrieves that command

Text colors

Idle defaults to black on white text, but colors text with special meanings. For the shell, these are shell output, shell error, user output, and user error. For Python code, at the shell prompt or in an editor, these are keywords, builtin class and function names, names following `class` and `def`, strings, and comments. For any text window, these are the cursor (when present), found text (when possible), and selected text.

IDLE also highlights the soft keywords **`match`**, **`case`**, and **`_`** in pattern-matching statements. However, this highlighting is not perfect and will be incorrect in some rare cases, including some `_`-s in `case` patterns.

Text coloring is done in the background, so uncolorized text is occasionally visible. To change the color scheme, use the Configure IDLE dialog Highlighting tab. The marking of debugger breakpoint lines in the editor and text in popups and dialogs is not user-configurable.

Startup and Code Execution

Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables **`IDLESTARTUP`** or **`PYTHONSTARTUP`**. IDLE first checks for `IDLESTARTUP`; if `IDLESTARTUP` is present the file referenced is run. If `IDLESTARTUP` is not present, IDLE checks for `PYTHONSTARTUP`. Files referenced by these environment variables are convenient places to store functions that are used frequently from the IDLE shell, or for executing import statements to import common modules.

In addition, `Tk` also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is `.Idle.py` and is looked for in the user's home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from IDLE's Python shell.

Command line usage

```
idle.py [-c command] [-d] [-e] [-h] [-i] [-r file] [-s]

-c command  run command in the shell window
-d          enable debugger and open shell window
-e          open editor window
-h          print help message with legal combinations a
-i          open shell window
-r file     run file in shell window
-s          run $IDLESTARTUP or $PYTHONSTARTUP first, ir
-t title    set title of shell window
-           run stdin in shell (- must be last option be
```

If there are arguments:

- If `-`, `-c`, or `r` is used, all arguments are placed in `sys.argv[1:...]` and `sys.argv[0]` is set to `''`, `'-c'`, or `'-r'`. No editor window is opened, even if that is the default set in the Options dialog.
- Otherwise, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.

Startup failure

IDLE uses a socket to communicate between the IDLE GUI process and the user code execution process. A connection must be established whenever the Shell starts or restarts. (The latter is indicated by a divider line that says 'RESTART'). If the user process fails to connect to the GUI process, it usually displays a `Tk` error box with a 'cannot connect' message that directs the user here. It then exits.

One specific connection failure on Unix systems results from misconfigured masquerading rules somewhere in a system's network setup. When IDLE is started from a terminal, one will see a message starting with `** Invalid host:`. The valid value is `127.0.0.1 (idlelib.rpc.LOCALHOST)`. One can diagnose with `tcpconnect -irv 127.0.0.1 6543` in one terminal window and `tcplisten <same args>` in another.

A common cause of failure is a user-written file with the same name as a standard library module, such as *random.py* and *tkinter.py*. When such a file is located in the same directory as a file that is about to be run, IDLE cannot import the stdlib file. The current fix is to rename the user file.

Though less common than in the past, an antivirus or firewall program may stop the connection. If the program cannot be taught to allow the connection, then it must be turned off for IDLE to work. It is safe to allow this internal connection because no data is visible on external ports. A similar problem is a network misconfiguration that blocks connections.

Python installation issues occasionally stop IDLE: multiple versions can clash, or a single installation might need admin access. If one undo the clash, or cannot or does not want to run as admin, it

might be easiest to completely remove Python and start over.

A zombie pythonw.exe process could be a problem. On Windows, use Task Manager to check for one and stop it if there is. Sometimes a restart initiated by a program crash or Keyboard Interrupt (control-C) may fail to connect. Dismissing the error box or using Restart Shell on the Shell menu may fix a temporary problem.

When IDLE first starts, it attempts to read user configuration files in `~/.idlerc/` (~ is one's home directory). If there is a problem, an error message should be displayed. Leaving aside random disk glitches, this can be prevented by never editing the files by hand. Instead, use the configuration dialog, under Options. Once there is an error in a user configuration file, the best solution may be to delete it and start over with the settings dialog.

If IDLE quits with no message, and it was not started from a console, try starting it from a console or terminal (`python -m idlelib`) and see if this results in an error message.

On Unix-based systems with tcl/tk older than `8.6.11` (see `About IDLE`) certain characters of certain fonts can cause a tk failure with a message to the terminal. This can happen either if one starts IDLE to edit a file with such a character or later when entering such a character. If one cannot upgrade tcl/tk, then re-configure IDLE to use a font that works better.

Running user code

With rare exceptions, the result of executing Python code with IDLE is intended to be the same as executing the same code by the default method, directly with Python in a text-mode system console or terminal window. However, the different interface and operation occasionally affect visible results. For instance, `sys.modules` starts with more entries, and `threading.active_count()` returns 2 instead of 1.

By default, IDLE runs user code in a separate OS process rather than in the user interface process that runs the shell and editor. In the execution process, it replaces `sys.stdin`, `sys.stdout`, and `sys.stderr` with objects that get input from and send output to

the Shell window. The original values stored in `sys.__stdin__`, `sys.__stdout__`, and `sys.__stderr__` are not touched, but may be `None`.

Sending print output from one process to a text widget in another is slower than printing to a system terminal in the same process. This has the most effect when printing multiple arguments, as the string for each argument, each separator, the newline are sent separately. For development, this is usually not a problem, but if one wants to print faster in IDLE, format and join together everything one wants displayed together and then print a single string. Both format strings and **`str.join()`** can help combine fields and lines.

IDLE's standard stream replacements are not inherited by subprocesses created in the execution process, whether directly by user code or by modules such as multiprocessing. If such subprocess use `input` from sys.stdin or `print` or `write` to sys.stdout or sys.stderr, IDLE should be started in a command line window. (On Windows, use `python` or `py` rather than `pythonw` or `pyw`.) The secondary subprocess will then be attached to that window for input and output.

If `sys` is reset by user code, such as with `importlib.reload(sys)`, IDLE's changes are lost and input from the keyboard and output to the screen will not work correctly.

When Shell has the focus, it controls the keyboard and screen. This is normally transparent, but functions that directly access the keyboard and screen will not work. These include system-specific functions that determine whether a key has been pressed and if so, which.

The IDLE code running in the execution process adds frames to the call stack that would not be there otherwise. IDLE wraps `sys.getrecursionlimit` and `sys.setrecursionlimit` to reduce the effect of the additional stack frames.

When user code raises SystemExit either directly or by calling sys.exit, IDLE returns to a Shell prompt instead of exiting.

User output in Shell

When a program outputs text, the result is determined by the corresponding output device. When IDLE executes user code, `sys.stdout` and `sys.stderr` are connected to the display area of IDLE's Shell. Some of its features are inherited from the underlying Tk Text widget. Others are programmed additions. Where it matters, Shell is designed for development rather than production runs.

For instance, Shell never throws away output. A program that sends unlimited output to Shell will eventually fill memory, resulting in a memory error. In contrast, some system text windows only keep the last n lines of output. A Windows console, for instance, keeps a user-settable 1 to 9999 lines, with 300 the default.

A Tk Text widget, and hence IDLE's Shell, displays characters (codepoints) in the BMP (Basic Multilingual Plane) subset of Unicode. Which characters are displayed with a proper glyph and which with a replacement box depends on the operating system and installed fonts. Tab characters cause the following text to begin after the next tab stop. (They occur every 8 'characters'). Newline characters cause following text to appear on a new line. Other control characters are ignored or displayed as a space, box, or something else, depending on the operating system and font. (Moving the text cursor through such output with arrow keys may exhibit some surprising spacing behavior.)

```
>>> s = 'a\tb\a<\x02><\r>\bc\nd'  # Enter 22 chars.
>>> len(s)
14
>>> s  # Display repr(s)
'a\tb\x07<\x02><\r>\x08c\nd'
>>> print(s, end='')  # Display s as is.
# Result varies by OS and font.  Try it.
```

The `repr` function is used for interactive echo of expression values. It returns an altered version of the input string in which control codes, some BMP codepoints, and all non-BMP codepoints are replaced with escape codes. As demonstrated above, it allows one to identify the characters in a string, regardless of how they are displayed.

Normal and error output are generally kept separate (on separate lines) from code input and each other. They each get different highlight colors.

For SyntaxError tracebacks, the normal '^' marking where the error was detected is replaced by coloring the text with an error highlight. When code run from a file causes other exceptions, one may right click on a traceback line to jump to the corresponding line in an IDLE editor. The file will be opened if necessary.

Shell has a special facility for squeezing output lines down to a 'Squeezed text' label. This is done automatically for output over N lines (N = 50 by default). N can be changed in the PyShell section of the General page of the Settings dialog. Output with fewer lines can be squeezed by right clicking on the output. This can be useful lines long enough to slow down scrolling.

Squeezed output is expanded in place by double-clicking the label. It can also be sent to the clipboard or a separate view window by right-clicking the label.

Developing tkinter applications

IDLE is intentionally different from standard Python in order to facilitate development of tkinter programs. Enter `import tkinter as tk; root = tk.Tk()` in standard Python and nothing appears. Enter the same in IDLE and a tk window appears. In standard Python, one must also enter `root.update()` to see the window. IDLE does the equivalent in the background, about 20 times a second, which is about every 50 milliseconds. Next enter `b = tk.Button(root, text='button'); b.pack()`. Again, nothing visibly changes in standard Python until one enters `root.update()`.

Most tkinter programs run `root.mainloop()`, which usually does not return until the tk app is destroyed. If the program is run with `python -i` or from an IDLE editor, a `>>>` shell prompt does not appear until `mainloop()` returns, at which time there is nothing left to interact with.

When running a tkinter program from an IDLE editor, one can

comment out the mainloop call. One then gets a shell prompt immediately and can interact with the live application. One just has to remember to re-enable the mainloop call when running in standard Python.

Running without a subprocess

By default, IDLE executes user code in a separate subprocess via a socket, which uses the internal loopback interface. This connection is not externally visible and no data is sent to or received from the internet. If firewall software complains anyway, you can ignore it.

If the attempt to make the socket connection fails, Idle will notify you. Such failures are sometimes transient, but if persistent, the problem may be either a firewall blocking the connection or misconfiguration of a particular system. Until the problem is fixed, one can run Idle with the -n command line switch.

If IDLE is started with the -n command line switch it will run in a single process and will not create the subprocess which runs the RPC Python execution server. This can be useful if Python cannot create the subprocess or the RPC socket interface on your platform. However, in this mode user code is not isolated from IDLE itself. Also, the environment is not restarted when Run/Run Module (F5) is selected. If your code has been modified, you must reload() the affected modules and re-import any specific items (e.g. from foo import baz) if the changes are to take effect. For these reasons, it is preferable to run IDLE with the default subprocess if at all possible.

Deprecated since version 3.4.

Help and Preferences

Help sources

Help menu entry “IDLE Help” displays a formatted html version of the IDLE chapter of the Library Reference. The result, in a read-only tkinter text window, is close to what one sees in a web browser. Navigate through the text with a mousewheel, the scrollbar, or up and down arrow keys held down. Or click the TOC (Table of

Contents) button and select a section header in the opened box.

Help menu entry “Python Docs” opens the extensive sources of help, including tutorials, available at `docs.python.org/x.y`, where ‘x.y’ is the currently running Python version. If your system has an off-line copy of the docs (this may be an installation option), that will be opened instead.

Selected URLs can be added or removed from the help menu at any time using the General tab of the Configure IDLE dialog.

Setting preferences

The font preferences, highlighting, keys, and general preferences can be changed via Configure IDLE on the Option menu. Non-default user settings are saved in a `.idlerc` directory in the user’s home directory. Problems caused by bad user configuration files are solved by editing or deleting one or more of the files in `.idlerc`.

On the Font tab, see the text sample for the effect of font face and size on multiple characters in multiple languages. Edit the sample to add other characters of personal interest. Use the sample to select monospaced fonts. If particular characters have problems in Shell or an editor, add them to the top of the sample and try changing first size and then font.

On the Highlights and Keys tab, select a built-in or custom color theme and key set. To use a newer built-in color theme or key set with older IDLEs, save it as a new custom theme or key set and it well be accessible to older IDLEs.

IDLE on macOS

Under System Preferences: Dock, one can set “Prefer tabs when opening documents” to “Always”. This setting is not compatible with the tk/tkinter GUI framework used by IDLE, and it breaks a few IDLE features.

Extensions

IDLE contains an extension facility. Preferences for extensions can be changed with the Extensions tab of the preferences dialog. See the beginning of config-extensions.def in the idlelib directory for further information. The only current default extension is zzdummy, an example also used for testing.

idlelib

Source code: Lib/idlelib [https://github.com/python/cpython/tree/3.11/Lib/idlelib]

The Lib/idlelib package implements the IDLE application. See the rest of this page for how to use IDLE.

The files in idlelib are described in idlelib/README.txt. Access it either in idlelib or click Help => About IDLE on the IDLE menu. This file also maps IDLE menu items to the code that implements the item. Except for files listed under 'Startup', the idlelib code is 'private' in sense that feature changes can be backported (see **PEP 434** [https://peps.python.org/pep-0434/]).

Development Tools

The modules described in this chapter help you write software. For example, the **pydoc** module takes a module and generates documentation based on the module's contents. The **doctest** and **unittest** modules contains frameworks for writing unit tests that automatically exercise code and verify that the expected output is produced. **2to3** can translate Python 2.x source code into valid Python 3.x code.

The list of modules described in this chapter is:

- **typing** — Support for type hints
  - Relevant PEPs
  - Type aliases
  - NewType
  - Callable
  - Generics
  - User-defined generic types
  - The **Any** type
  - Nominal vs structural subtyping
  - Module contents
    - Special typing primitives
      - Special types
      - Special forms
      - Building generic types
      - Other special directives
    - Generic concrete collections
      - Corresponding to built-in types
      - Corresponding to types in **collections**
      - Other concrete types

        - Abstract Base Classes
            - Corresponding to collections in **collections.abc**
            - Corresponding to other types in **collections.abc**
            - Asynchronous programming
            - Context manager types
        - Protocols
        - Functions and decorators
        - Introspection helpers
        - Constant
    - Deprecation Timeline of Major Features

- **pydoc** — Documentation generator and online help system
- Python Development Mode
- Effects of the Python Development Mode
- ResourceWarning Example
- Bad file descriptor error example
- **doctest** — Test interactive Python examples
    - Simple Usage: Checking Examples in Docstrings
    - Simple Usage: Checking Examples in a Text File
    - How It Works
        - Which Docstrings Are Examined?
        - How are Docstring Examples Recognized?
        - What's the Execution Context?
        - What About Exceptions?
        - Option Flags
        - Directives
        - Warnings
    - Basic API
    - Unittest API
    - Advanced API
        - DocTest Objects
        - Example Objects

        - DocTestFinder objects
        - DocTestParser objects
        - DocTestRunner objects
        - OutputChecker objects
    - Debugging
    - Soapbox
- **unittest** — Unit testing framework
    - Basic example
    - Command-Line Interface
        - Command-line options
    - Test Discovery
    - Organizing test code
    - Re-using old test code
    - Skipping tests and expected failures
    - Distinguishing test iterations using subtests
    - Classes and functions
        - Test cases
            - Deprecated aliases

`typing` — Support for type hints

New in version 3.5.

Source code: Lib/typing.py [https://github.com/python/cpython/tree/3.11/Lib/typing.py]

Note

The Python runtime does not enforce function and variable type annotations. They can be used by third party tools such as type checkers, IDEs, linters, etc.

This module provides runtime support for type hints. The most fundamental support consists of the types `Any`, `Union`, `Callable`, `TypeVar`, and `Generic`. For a full specification, please see **PEP 484** [https://peps.python.org/pep-0484/]. For a simplified introduction to type hints, see **PEP 483** [https://peps.python.org/pep-0483/].

The function below takes and returns a string and is annotated as follows:

```
def greeting(name: str) -> str:
    return 'Hello ' + name
```

In the function `greeting`, the argument `name` is expected to be of type `str` and the return type `str`. Subtypes are accepted as arguments.

New features are frequently added to the `typing` module. The typing_extensions [https://pypi.org/project/typing-extensions/] package provides backports of these new features to older versions of

Python.

For a summary of deprecated features and a deprecation timeline, please see Deprecation Timeline of Major Features.

See also

The documentation at https://typing.readthedocs.io/ serves as useful reference for type system features, useful typing related tools and typing best practices.

Relevant PEPs

Since the initial introduction of type hints in **PEP 484** [https://peps.python.org/pep-0484/] and **PEP 483** [https://peps.python.org/pep-0483/], a number of PEPs have modified and enhanced Python's framework for type annotations. These include:

- **PEP 526** [https://peps.python.org/pep-0526/]: Syntax for Variable Annotations
  Introducing syntax for annotating variables outside of function definitions, and `ClassVar`

- **PEP 544** [https://peps.python.org/pep-0544/]: Protocols: Structural subtyping (static duck typing)
  Introducing `Protocol` and the `@runtime_checkable` decorator

- **PEP 585** [https://peps.python.org/pep-0585/]: Type Hinting Generics In Standard Collections
  Introducing `types.GenericAlias` and the ability to use standard library classes as generic types

- **PEP 586** [https://peps.python.org/pep-0586/]: Literal Types
  Introducing `Literal`

- **PEP 589** [https://peps.python.org/pep-0589/]: TypedDict: Type Hints for Dictionaries with a Fixed Set of Keys

Introducing **`TypedDict`**

- **PEP 591** [https://peps.python.org/pep-0591/]: Adding a final qualifier to typing
  Introducing **`Final`** and the **`@final`** decorator

- **PEP 593** [https://peps.python.org/pep-0593/]: Flexible function and variable annotations
  Introducing **`Annotated`**

- **PEP 604** [https://peps.python.org/pep-0604/]: Allow writing union types as `X | Y`
  Introducing **`types.UnionType`** and the ability to use the binary-or operator `|` to signify a union of types

- **PEP 612** [https://peps.python.org/pep-0612/]: Parameter Specification Variables
  Introducing **`ParamSpec`** and **`Concatenate`**

- **PEP 613** [https://peps.python.org/pep-0613/]: Explicit Type Aliases
  Introducing **`TypeAlias`**

- **PEP 646** [https://peps.python.org/pep-0646/]: Variadic Generics
  Introducing **`TypeVarTuple`**

- **PEP 647** [https://peps.python.org/pep-0647/]: User-Defined Type Guards
  Introducing **`TypeGuard`**

- **PEP 655** [https://peps.python.org/pep-0655/]: Marking individual TypedDict items as required or potentially missing
  Introducing **`Required`** and **`NotRequired`**

- **PEP 673** [https://peps.python.org/pep-0673/]: Self type
  Introducing **`Self`**

- **PEP 675** [https://peps.python.org/pep-0675/]: Arbitrary Literal String Type
  Introducing **`LiteralString`**

- **PEP 681** [https://peps.python.org/pep-0681/]: Data Class Transforms
  Introducing the `@dataclass_transform` decorator

Type aliases

A type alias is defined by assigning the type to the alias. In this example, `Vector` and `list[float]` will be treated as interchangeable synonyms:

```
Vector = list[float]

def scale(scalar: float, vector: Vector) -> Vector:
    return [scalar * num for num in vector]

# passes type checking; a list of floats qualifies as a
new_vector = scale(2.0, [1.0, -4.2, 5.4])
```

Type aliases are useful for simplifying complex type signatures. For example:

```
from collections.abc import Sequence

ConnectionOptions = dict[str, str]
Address = tuple[str, int]
Server = tuple[Address, ConnectionOptions]

def broadcast_message(message: str, servers: Sequence[Se
    ...

# The static type checker will treat the previous type s
# being exactly equivalent to this one.
def broadcast_message(
        message: str,
        servers: Sequence[tuple[tuple[str, int], dict[st
    ...
```

Note that `None` as a type hint is a special case and is replaced by `type(None)`.

NewType

Use the **`NewType`** helper to create distinct types:

```
from typing import NewType

UserId = NewType('UserId', int)
some_id = UserId(524313)
```

The static type checker will treat the new type as if it were a subclass of the original type. This is useful in helping catch logical errors:

```
def get_user_name(user_id: UserId) -> str:
    ...

# passes type checking
user_a = get_user_name(UserId(42351))

# fails type checking; an int is not a UserId
user_b = get_user_name(-1)
```

You may still perform all `int` operations on a variable of type `UserId`, but the result will always be of type `int`. This lets you pass in a `UserId` wherever an `int` might be expected, but will prevent you from accidentally creating a `UserId` in an invalid way:

```
# 'output' is of type 'int', not 'UserId'
output = UserId(23413) + UserId(54341)
```

Note that these checks are enforced only by the static type checker. At runtime, the statement `Derived = NewType('Derived', Base)` will make `Derived` a callable that immediately returns whatever parameter you pass it. That means the expression `Derived(some_value)` does not create a new class or introduce much overhead beyond that of a regular function call.

More precisely, the expression `some_value is Derived(some_value)` is always true at runtime.

It is invalid to create a subtype of `Derived`:

```
from typing import NewType

UserId = NewType('UserId', int)

# Fails at runtime and does not pass type checking
class AdminUserId(UserId): pass
```

However, it is possible to create a **`NewType`** based on a 'derived' `NewType`:

```
from typing import NewType

UserId = NewType('UserId', int)

ProUserId = NewType('ProUserId', UserId)
```

and typechecking for `ProUserId` will work as expected.

See **PEP 484** [https://peps.python.org/pep-0484/] for more details.

Note

Recall that the use of a type alias declares two types to be *equivalent* to one another. Doing `Alias = Original` will make the static type checker treat `Alias` as being *exactly equivalent* to `Original` in all cases. This is useful when you want to simplify complex type signatures.

In contrast, `NewType` declares one type to be a *subtype* of another. Doing `Derived = NewType('Derived', Original)` will make the static type checker treat `Derived` as a *subclass* of `Original`, which means a value of type `Original` cannot be used in places where a value of type `Derived` is expected. This is useful when you want to prevent logic errors with minimal runtime cost.

New in version 3.5.2.

Changed in version 3.10: `NewType` is now a class rather than a function. There is some additional runtime cost when calling `NewType` over a regular function. However, this cost will be reduced in 3.11.0.

Callable

Frameworks expecting callback functions of specific signatures might be type hinted using `Callable[[Arg1Type, Arg2Type], ReturnType]`.

For example:

```
from collections.abc import Callable

def feeder(get_next_item: Callable[[], str]) -> None:
    # Body

def async_query(on_success: Callable[[int], None],
                on_error: Callable[[int, Exception], Nor
    # Body

async def on_update(value: str) -> None:
    # Body
callback: Callable[[str], Awaitable[None]] = on_update
```

It is possible to declare the return type of a callable without specifying the call signature by substituting a literal ellipsis for the list of arguments in the type hint: `Callable[..., ReturnType]`.

Callables which take other callables as arguments may indicate that their parameter types are dependent on each other using **`ParamSpec`**. Additionally, if that callable adds or removes arguments from other callables, the **`Concatenate`** operator may be used. They take the form `Callable[ParamSpecVariable, ReturnType]` and `Callable[Concatenate[Arg1Type, Arg2Type, ..., ParamSpecVariable], ReturnType]` respectively.

Changed in version 3.10: `Callable` now supports **`ParamSpec`** and **`Concatenate`**. See **PEP 612** [https://peps.python.org/pep-0612/] for more details.

See also

The documentation for **`ParamSpec`** and **`Concatenate`** provides examples of usage in `Callable`.

Generics

Since type information about objects kept in containers cannot be statically inferred in a generic way, abstract base classes have been extended to support subscription to denote expected types for container elements.

```
from collections.abc import Mapping, Sequence

def notify_by_email(employees: Sequence[Employee],
                    overrides: Mapping[str, str]) -> Nor
```

Generics can be parameterized by using a factory available in typing called **`TypeVar`**.

```
from collections.abc import Sequence
from typing import TypeVar

T = TypeVar('T')      # Declare type variable

def first(l: Sequence[T]) -> T:   # Generic function
    return l[0]
```

User-defined generic types

A user-defined class can be defined as a generic class.

```
from typing import TypeVar, Generic
from logging import Logger
```

```
T = TypeVar('T')

class LoggedVar(Generic[T]):
    def __init__(self, value: T, name: str, logger: Logg
        self.name = name
        self.logger = logger
        self.value = value

    def set(self, new: T) -> None:
        self.log('Set ' + repr(self.value))
        self.value = new

    def get(self) -> T:
        self.log('Get ' + repr(self.value))
        return self.value

    def log(self, message: str) -> None:
        self.logger.info('%s: %s', self.name, message)
```

`Generic[T]` as a base class defines that the class `LoggedVar` takes a single type parameter `T`. This also makes `T` valid as a type within the class body.

The **`Generic`** base class defines **`__class_getitem__()`** so that `LoggedVar[T]` is valid as a type:

```
from collections.abc import Iterable

def zero_all_vars(vars: Iterable[LoggedVar[int]]) -> Nor
    for var in vars:
        var.set(0)
```

A generic type can have any number of type variables. All varieties of **`TypeVar`** are permissible as parameters for a generic type:

```
from typing import TypeVar, Generic, Sequence

T = TypeVar('T', contravariant=True)
B = TypeVar('B', bound=Sequence[bytes], covariant=True)
```

```
S = TypeVar('S', int, str)

class WeirdTrio(Generic[T, B, S]):
    ...
```

Each type variable argument to **`Generic`** must be distinct. This is thus invalid:

```
from typing import TypeVar, Generic
...

T = TypeVar('T')

class Pair(Generic[T, T]):   # INVALID
    ...
```

You can use multiple inheritance with **`Generic`**:

```
from collections.abc import Sized
from typing import TypeVar, Generic

T = TypeVar('T')

class LinkedList(Sized, Generic[T]):
    ...
```

When inheriting from generic classes, some type variables could be fixed:

```
from collections.abc import Mapping
from typing import TypeVar

T = TypeVar('T')

class MyDict(Mapping[str, T]):
    ...
```

In this case `MyDict` has a single parameter, `T`.

Using a generic class without specifying type parameters assumes

Any for each position. In the following example, `MyIterable` is not generic but implicitly inherits from `Iterable[Any]`:

```
from collections.abc import Iterable

class MyIterable(Iterable): # Same as Iterable[Any]
```

User defined generic type aliases are also supported. Examples:

```
from collections.abc import Iterable
from typing import TypeVar
S = TypeVar('S')
Response = Iterable[S] | int

# Return type here is same as Iterable[str] | int
def response(query: str) -> Response[str]:
    ...

T = TypeVar('T', int, float, complex)
Vec = Iterable[tuple[T, T]]

def inproduct(v: Vec[T]) -> T: # Same as Iterable[tuple[
    return sum(x*y for x, y in v)
```

Changed in version 3.7: **Generic** no longer has a custom metaclass.

User-defined generics for parameter expressions are also supported via parameter specification variables in the form `Generic[P]`. The behavior is consistent with type variables' described above as parameter specification variables are treated by the typing module as a specialized type variable. The one exception to this is that a list of types can be used to substitute a **ParamSpec**:

```
>>> from typing import Generic, ParamSpec, TypeVar

>>> T = TypeVar('T')
>>> P = ParamSpec('P')

>>> class Z(Generic[T, P]): ...
...
```

```
>>> Z[int, [dict, float]]
__main__.Z[int, (<class 'dict'>, <class 'float'>)]
```

Furthermore, a generic with only one parameter specification variable will accept parameter lists in the forms `X[[Type1, Type2, ...]]` and also `X[Type1, Type2, ...]` for aesthetic reasons. Internally, the latter is converted to the former, so the following are equivalent:

```
>>> class X(Generic[P]): ...
...
>>> X[int, str]
__main__.X[(<class 'int'>, <class 'str'>)]
>>> X[[int, str]]
__main__.X[(<class 'int'>, <class 'str'>)]
```

Do note that generics with **`ParamSpec`** may not have correct `__parameters__` after substitution in some cases because they are intended primarily for static type checking.

Changed in version 3.10: **`Generic`** can now be parameterized over parameter expressions. See **`ParamSpec`** and **PEP 612** [https://peps.python.org/pep-0612/] for more details.

A user-defined generic class can have ABCs as base classes without a metaclass conflict. Generic metaclasses are not supported. The outcome of parameterizing generics is cached, and most types in the typing module are hashable and comparable for equality.

The **`Any`** type

A special kind of type is **`Any`**. A static type checker will treat every type as being compatible with **`Any`** and **`Any`** as being compatible with every type.

This means that it is possible to perform any operation or method call on a value of type **`Any`** and assign it to any variable:

```
from typing import Any
```

```
a: Any = None
a = []          # OK
a = 2           # OK

s: str = ''
s = a           # OK

def foo(item: Any) -> int:
    # Passes type checking; 'item' could be any type,
    # and that type might have a 'bar' method
    item.bar()
    ...
```

Notice that no type checking is performed when assigning a value of type **`Any`** to a more precise type. For example, the static type checker did not report an error when assigning `a` to `s` even though `s` was declared to be of type **`str`** and receives an **`int`** value at runtime!

Furthermore, all functions without a return type or parameter types will implicitly default to using **`Any`**:

```
def legacy_parser(text):
    ...
    return data

# A static type checker will treat the above
# as having the same signature as:
def legacy_parser(text: Any) -> Any:
    ...
    return data
```

This behavior allows **`Any`** to be used as an *escape hatch* when you need to mix dynamically and statically typed code.

Contrast the behavior of **`Any`** with the behavior of **`object`**. Similar to **`Any`**, every type is a subtype of **`object`**. However, unlike **`Any`**, the reverse is not true: **`object`** is *not* a subtype of every other type.

That means when the type of a value is **`object`**, a type checker will reject almost all operations on it, and assigning it to a variable (or using it as a return value) of a more specialized type is a type error. For example:

```
def hash_a(item: object) -> int:
    # Fails type checking; an object does not have a 'ma
    item.magic()
    ...

def hash_b(item: Any) -> int:
    # Passes type checking
    item.magic()
    ...

# Passes type checking, since ints and strs are subclass
hash_a(42)
hash_a("foo")

# Passes type checking, since Any is compatible with all
hash_b(42)
hash_b("foo")
```

Use **`object`** to indicate that a value could be any type in a typesafe manner. Use **`Any`** to indicate that a value is dynamically typed.

Nominal vs structural subtyping

Initially **PEP 484** [https://peps.python.org/pep-0484/] defined the Python static type system as using *nominal subtyping*. This means that a class `A` is allowed where a class `B` is expected if and only if `A` is a subclass of `B`.

This requirement previously also applied to abstract base classes, such as **`Iterable`**. The problem with this approach is that a class had to be explicitly marked to support them, which is unpythonic and unlike what one would normally do in idiomatic dynamically typed Python code. For example, this conforms to **PEP 484** [https://

peps.python.org/pep-0484/]:

```
from collections.abc import Sized, Iterable, Iterator

class Bucket(Sized, Iterable[int]):
    ...
    def __len__(self) -> int: ...
    def __iter__(self) -> Iterator[int]: ...
```

PEP 544 [https://peps.python.org/pep-0544/] allows to solve this problem by allowing users to write the above code without explicit base classes in the class definition, allowing `Bucket` to be implicitly considered a subtype of both `Sized` and `Iterable[int]` by static type checkers. This is known as *structural subtyping* (or static duck-typing):

```
from collections.abc import Iterator, Iterable

class Bucket:  # Note: no base classes
    ...
    def __len__(self) -> int: ...
    def __iter__(self) -> Iterator[int]: ...

def collect(items: Iterable[int]) -> int: ...
result = collect(Bucket())  # Passes type check
```

Moreover, by subclassing a special class **`Protocol`**, a user can define new custom protocols to fully enjoy structural subtyping (see examples below).

Module contents

The module defines the following classes, functions and decorators.

Note

This module defines several types that are subclasses of pre-existing standard library classes which also extend **`Generic`** to support type variables inside `[]`. These types became redundant

in Python 3.9 when the corresponding pre-existing classes were enhanced to support `[]`.

The redundant types are deprecated as of Python 3.9 but no deprecation warnings will be issued by the interpreter. It is expected that type checkers will flag the deprecated types when the checked program targets Python 3.9 or newer.

The deprecated types will be removed from the **`typing`** module in the first Python version released 5 years after the release of Python 3.9.0. See details in **PEP 585** [https://peps.python.org/pep-0585/]—*Type Hinting Generics In Standard Collections*.

Special typing primitives

Special types

These can be used as types in annotations and do not support `[]`.

typing.Any

Special type indicating an unconstrained type.

- Every type is compatible with **`Any`**.
- **`Any`** is compatible with every type.

Changed in version 3.11: **`Any`** can now be used as a base class. This can be useful for avoiding type checker errors with classes that can duck type anywhere or are highly dynamic.

typing.LiteralString

Special type that includes only literal strings. A string literal is compatible with `LiteralString`, as is another `LiteralString`, but an object typed as just `str` is not. A string created by composing `LiteralString`-typed objects is also acceptable as a `LiteralString`.

Example:

```
def run_query(sql: LiteralString) -> ...
    ...
```

```
def caller(arbitrary_string: str, literal_string: L
    run_query("SELECT * FROM students")  # ok
    run_query(literal_string)  # ok
    run_query("SELECT * FROM " + literal_string)  #
    run_query(arbitrary_string)  # type checker err
    run_query(  # type checker error
        f"SELECT * FROM students WHERE name = {arbi
    )
```

This is useful for sensitive APIs where arbitrary user-generated strings could generate problems. For example, the two cases above that generate type checker errors could be vulnerable to an SQL injection attack.

See **PEP 675** [https://peps.python.org/pep-0675/] for more details.

New in version 3.11.

typing.Never

The bottom type [https://en.wikipedia.org/wiki/Bottom_type], a type that has no members.

This can be used to define a function that should never be called, or a function that never returns:

```
from typing import Never

def never_call_me(arg: Never) -> None:
    pass

def int_or_str(arg: int | str) -> None:
    never_call_me(arg)  # type checker error
    match arg:
        case int():
            print("It's an int")
        case str():
            print("It's a str")
        case _:
```

```
                never_call_me(arg)  # ok, arg is of typ
```

New in version 3.11: On older Python versions, **NoReturn** may be used to express the same concept. `Never` was added to make the intended meaning more explicit.

typing.NoReturn

Special type indicating that a function never returns. For example:

```
from typing import NoReturn

def stop() -> NoReturn:
    raise RuntimeError('no way')
```

`NoReturn` can also be used as a bottom type [https://en.wikipedia.org/wiki/Bottom_type], a type that has no values. Starting in Python 3.11, the **Never** type should be used for this concept instead. Type checkers should treat the two equivalently.

New in version 3.5.4.

New in version 3.6.2.

typing.Self

Special type to represent the current enclosed class. For example:

```
from typing import Self

class Foo:
   def return_self(self) -> Self:
      ...
      return self
```

This annotation is semantically equivalent to the following, albeit in a more succinct fashion:

```
from typing import TypeVar
```

```
Self = TypeVar("Self", bound="Foo")

class Foo:
   def return_self(self: Self) -> Self:
      ...
      return self
```

In general if something currently follows the pattern of:

```
class Foo:
   def return_self(self) -> "Foo":
      ...
      return self
```

You should use **`Self`** as calls to `SubclassOfFoo.return_self` would have `Foo` as the return type and not `SubclassOfFoo`.

Other common use cases include:

- **`classmethod`**s that are used as alternative constructors and return instances of the `cls` parameter.
- Annotating an **`__enter__()`** method which returns self.

See **PEP 673** [https://peps.python.org/pep-0673/] for more details.

New in version 3.11.

typing.TypeAlias

Special annotation for explicitly declaring a type alias. For example:

```
from typing import TypeAlias

Factors: TypeAlias = list[int]
```

See **PEP 613** [https://peps.python.org/pep-0613/] for more details about explicit type aliases.

New in version 3.10.

Special forms

These can be used as types in annotations using `[]`, each having a unique syntax.

typing.Tuple

Tuple type; `Tuple[X, Y]` is the type of a tuple of two items with the first item of type X and the second of type Y. The type of the empty tuple can be written as `Tuple[()]`.

Example: `Tuple[T1, T2]` is a tuple of two elements corresponding to type variables T1 and T2. `Tuple[int, float, str]` is a tuple of an int, a float and a string.

To specify a variable-length tuple of homogeneous type, use literal ellipsis, e.g. `Tuple[int, ...]`. A plain **`Tuple`** is equivalent to `Tuple[Any, ...]`, and in turn to **`tuple`**.

Deprecated since version 3.9: **`builtins.tuple`** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

typing.Union

Union type; `Union[X, Y]` is equivalent to `X | Y` and means either X or Y.

To define a union, use e.g. `Union[int, str]` or the shorthand `int | str`. Using that shorthand is recommended. Details:

- The arguments must be types and there must be at least one.
- Unions of unions are flattened, e.g.:

  ```
  Union[Union[int, str], float] == Union[int, str
  ```

- Unions of a single argument vanish, e.g.:

```
Union[int] == int  # The constructor actually r
```

- Redundant arguments are skipped, e.g.:

  ```
  Union[int, str, int] == Union[int, str] == int
  ```

- When comparing unions, the argument order is ignored, e.g.:

  ```
  Union[int, str] == Union[str, int]
  ```

- You cannot subclass or instantiate a `Union`.

- You cannot write `Union[X][Y]`.

Changed in version 3.7: Don't remove explicit subclasses from unions at runtime.

Changed in version 3.10: Unions can now be written as `X | Y`. See union type expressions.

typing.Optional

Optional type.

`Optional[X]` is equivalent to `X | None` (or `Union[X, None]`).

Note that this is not the same concept as an optional argument, which is one that has a default. An optional argument with a default does not require the `Optional` qualifier on its type annotation just because it is optional. For example:

```
def foo(arg: int = 0) -> None:
    ...
```

On the other hand, if an explicit value of `None` is allowed, the use of `Optional` is appropriate, whether the argument is optional or not. For example:

```
def foo(arg: Optional[int] = None) -> None:
```

...

Changed in version 3.10: Optional can now be written as `X | None`. See union type expressions.

typing.Callable

Callable type; `Callable[[int], str]` is a function of (int) -> str.

The subscription syntax must always be used with exactly two values: the argument list and the return type. The argument list must be a list of types or an ellipsis; the return type must be a single type.

There is no syntax to indicate optional or keyword arguments; such function types are rarely used as callback types. `Callable[..., ReturnType]` (literal ellipsis) can be used to type hint a callable taking any number of arguments and returning `ReturnType`. A plain **`Callable`** is equivalent to `Callable[..., Any]`, and in turn to **`collections.abc.Callable`**.

Callables which take other callables as arguments may indicate that their parameter types are dependent on each other using **`ParamSpec`**. Additionally, if that callable adds or removes arguments from other callables, the **`Concatenate`** operator may be used. They take the form `Callable[ParamSpecVariable, ReturnType]` and `Callable[Concatenate[Arg1Type, Arg2Type, ..., ParamSpecVariable], ReturnType]` respectively.

Deprecated since version 3.9: **`collections.abc.Callable`** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

Changed in version 3.10: `Callable` now supports **`ParamSpec`** and **`Concatenate`**. See **PEP 612** [https://peps.python.org/pep-0612/] for more details.

See also

The documentation for **ParamSpec** and **Concatenate** provide examples of usage with `Callable`.

typing.Concatenate

Used with **Callable** and **ParamSpec** to type annotate a higher order callable which adds, removes, or transforms parameters of another callable. Usage is in the form `Concatenate[Arg1Type, Arg2Type, ..., ParamSpecVariable]`. `Concatenate` is currently only valid when used as the first argument to a **Callable**. The last parameter to `Concatenate` must be a **ParamSpec** or ellipsis (`...`).

For example, to annotate a decorator `with_lock` which provides a **threading.Lock** to the decorated function, `Concatenate` can be used to indicate that `with_lock` expects a callable which takes in a `Lock` as the first argument, and returns a callable with a different type signature. In this case, the **ParamSpec** indicates that the returned callable's parameter types are dependent on the parameter types of the callable being passed in:

```
from collections.abc import Callable
from threading import Lock
from typing import Concatenate, ParamSpec, TypeVar

P = ParamSpec('P')
R = TypeVar('R')

# Use this lock to ensure that only one thread is e
# at any time.
my_lock = Lock()

def with_lock(f: Callable[Concatenate[Lock, P], R])
    '''A type-safe decorator which provides a lock.
    def inner(*args: P.args, **kwargs: P.kwargs) ->
        # Provide the lock as the first argument.
        return f(my_lock, *args, **kwargs)
```

```
        return inner

    @with_lock
    def sum_threadsafe(lock: Lock, numbers: list[float]
        '''Add a list of numbers together in a thread-s
        with lock:
            return sum(numbers)

    # We don't need to pass in the lock ourselves thank
    sum_threadsafe([1.1, 2.2, 3.3])
```

New in version 3.10.

See also

- **PEP 612** [https://peps.python.org/pep-0612/] – Parameter Specification Variables (the PEP which introduced `ParamSpec` and `Concatenate`).
- **`ParamSpec`** and **`Callable`**.

class typing.Type(*Generic[CT_co]*)

A variable annotated with `C` may accept a value of type `C`. In contrast, a variable annotated with `Type[C]` may accept values that are classes themselves – specifically, it will accept the *class object* of `C`. For example:

```
a = 3         # Has type 'int'
b = int       # Has type 'Type[int]'
c = type(a)   # Also has type 'Type[int]'
```

Note that `Type[C]` is covariant:

```
class User: ...
class BasicUser(User): ...
class ProUser(User): ...
class TeamUser(User): ...

# Accepts User, BasicUser, ProUser, TeamUser, ...
```

```
def make_new_user(user_class: Type[User]) -> User:
    # ...
    return user_class()
```

The fact that `Type[C]` is covariant implies that all subclasses of `C` should implement the same constructor signature and class method signatures as `C`. The type checker should flag violations of this, but should also allow constructor calls in subclasses that match the constructor calls in the indicated base class. How the type checker is required to handle this particular case may change in future revisions of **PEP 484** [https://peps.python.org/pep-0484/].

The only legal parameters for **`Type`** are classes, **`Any`**, type variables, and unions of any of these types. For example:

```
def new_non_team_user(user_class: Type[BasicUser |
```

`Type[Any]` is equivalent to `Type` which in turn is equivalent to `type`, which is the root of Python's metaclass hierarchy.

New in version 3.5.2.

Deprecated since version 3.9: **`builtins.type`** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

typing.Literal

A type that can be used to indicate to type checkers that the corresponding variable or function parameter has a value equivalent to the provided literal (or one of several literals). For example:

```
def validate_simple(data: Any) -> Literal[True]:  #
    ...

MODE = Literal['r', 'rb', 'w', 'wb']
def open_helper(file: str, mode: MODE) -> str:
    ...
```

```
open_helper('/some/path', 'r')  # Passes type check
open_helper('/other/path', 'typo')  # Error in type
```

`Literal[...]` cannot be subclassed. At runtime, an arbitrary value is allowed as type argument to `Literal[...]`, but type checkers may impose restrictions. See **PEP 586** [https://peps.python.org/pep-0586/] for more details about literal types.

New in version 3.8.

Changed in version 3.9.1: `Literal` now de-duplicates parameters. Equality comparisons of `Literal` objects are no longer order dependent. `Literal` objects will now raise a **`TypeError`** exception during equality comparisons if one of their parameters are not hashable.

typing.ClassVar

Special type construct to mark class variables.

As introduced in **PEP 526** [https://peps.python.org/pep-0526/], a variable annotation wrapped in ClassVar indicates that a given attribute is intended to be used as a class variable and should not be set on instances of that class. Usage:

```
class Starship:
    stats: ClassVar[dict[str, int]] = {} # class va
    damage: int = 10                     # instance
```

`ClassVar` accepts only types and cannot be further subscribed.

`ClassVar` is not a class itself, and should not be used with **`isinstance()`** or **`issubclass()`**. **`ClassVar`** does not change Python runtime behavior, but it can be used by third-party type checkers. For example, a type checker might flag the following code as an error:

```
enterprise_d = Starship(3000)
enterprise_d.stats = {} # Error, setting class vari
```

```
Starship.stats = {}      # This is OK
```

New in version 3.5.3.

typing.Final

A special typing construct to indicate to type checkers that a name cannot be re-assigned or overridden in a subclass. For example:

```
MAX_SIZE: Final = 9000
MAX_SIZE += 1  # Error reported by type checker

class Connection:
    TIMEOUT: Final[int] = 10

class FastConnector(Connection):
    TIMEOUT = 1  # Error reported by type checker
```

There is no runtime checking of these properties. See **PEP 591** [https://peps.python.org/pep-0591/] for more details.

New in version 3.8.

typing.Required

typing.NotRequired

Special typing constructs that mark individual keys of a **`TypedDict`** as either required or non-required respectively.

See **`TypedDict`** and **PEP 655** [https://peps.python.org/pep-0655/] for more details.

New in version 3.11.

typing.Annotated

A type, introduced in **PEP 593** [https://peps.python.org/pep-0593/] (`Flexible function and variable annotations`), to decorate existing types with context-specific metadata (possibly multiple pieces of it, as `Annotated` is variadic).

Specifically, a type `T` can be annotated with metadata `x` via the typehint `Annotated[T, x]`. This metadata can be used for either static analysis or at runtime. If a library (or tool) encounters a typehint `Annotated[T, x]` and has no special logic for metadata `x`, it should ignore it and simply treat the type as `T`. Unlike the `no_type_check` functionality that currently exists in the `typing` module which completely disables typechecking annotations on a function or a class, the `Annotated` type allows for both static typechecking of `T` (which can safely ignore `x`) together with runtime access to `x` within a specific application.

Ultimately, the responsibility of how to interpret the annotations (if at all) is the responsibility of the tool or library encountering the `Annotated` type. A tool or library encountering an `Annotated` type can scan through the annotations to determine if they are of interest (e.g., using `isinstance()`).

When a tool or a library does not support annotations or encounters an unknown annotation it should just ignore it and treat annotated type as the underlying type.

It's up to the tool consuming the annotations to decide whether the client is allowed to have several annotations on one type and how to merge those annotations.

Since the `Annotated` type allows you to put several annotations of the same (or different) type(s) on any node, the tools or libraries consuming those annotations are in charge of dealing with potential duplicates. For example, if you are doing value range analysis you might allow this:

```
T1 = Annotated[int, ValueRange(-10, 5)]
T2 = Annotated[T1, ValueRange(-20, 3)]
```

Passing `include_extras=True` to **`get_type_hints()`** lets one access the extra annotations at runtime.

The details of the syntax:

- The first argument to `Annotated` must be a valid type
- Multiple type annotations are supported (`Annotated` supports variadic arguments):

```
Annotated[int, ValueRange(3, 10), ctype("char")
```

- `Annotated` must be called with at least two arguments (`Annotated[int]` is not valid)
- The order of the annotations is preserved and matters for equality checks:

```
Annotated[int, ValueRange(3, 10), ctype("char")
    int, ctype("char"), ValueRange(3, 10)
]
```

- Nested `Annotated` types are flattened, with metadata ordered starting with the innermost annotation:

```
Annotated[Annotated[int, ValueRange(3, 10)], ct
    int, ValueRange(3, 10), ctype("char")
]
```

- Duplicated annotations are not removed:

```
Annotated[int, ValueRange(3, 10)] != Annotated[
    int, ValueRange(3, 10), ValueRange(3, 10)
]
```

- `Annotated` can be used with nested and generic aliases:

```
T = TypeVar('T')
Vec = Annotated[list[tuple[T, T]], MaxLen(10)]
V = Vec[int]

V == Annotated[list[tuple[int, int]], MaxLen(10
```

New in version 3.9.

typing.TypeGuard

Special typing form used to annotate the return type of a user-defined type guard function. `TypeGuard` only accepts a single type argument. At runtime, functions marked this way should return a boolean.

`TypeGuard` aims to benefit *type narrowing* – a technique used by static type checkers to determine a more precise type of an expression within a program's code flow. Usually type narrowing is done by analyzing conditional code flow and applying the narrowing to a block of code. The conditional expression here is sometimes referred to as a "type guard":

```
def is_str(val: str | float):
    # "isinstance" type guard
    if isinstance(val, str):
        # Type of ``val`` is narrowed to ``str``
        ...
    else:
        # Else, type of ``val`` is narrowed to ``fl
        ...
```

Sometimes it would be convenient to use a user-defined boolean function as a type guard. Such a function should use `TypeGuard[...]` as its return type to alert static type checkers to this intention.

Using `-> TypeGuard` tells the static type checker that for a given function:

1. The return value is a boolean.
2. If the return value is `True`, the type of its argument is the type inside `TypeGuard`.

For example:

```
def is_str_list(val: list[object]) -> TypeGuard[lis
    '''Determines whether all objects in the list a
    return all(isinstance(x, str) for x in val)
```

```
def func1(val: list[object]):
    if is_str_list(val):
        # Type of ``val`` is narrowed to ``list[str
        print(" ".join(val))
    else:
        # Type of ``val`` remains as ``list[object]
        print("Not a list of strings!")
```

If `is_str_list` is a class or instance method, then the type in `TypeGuard` maps to the type of the second parameter after `cls` or `self`.

In short, the form `def foo(arg: TypeA) -> TypeGuard[TypeB]: ...`, means that if `foo(arg)` returns `True`, then `arg` narrows from `TypeA` to `TypeB`.

Note

`TypeB` need not be a narrower form of `TypeA` – it can even be a wider form. The main reason is to allow for things like narrowing `list[object]` to `list[str]` even though the latter is not a subtype of the former, since `list` is invariant. The responsibility of writing type-safe type guards is left to the user.

`TypeGuard` also works with type variables. See **PEP 647** [https://peps.python.org/pep-0647/] for more details.

New in version 3.10.

Building generic types

These are not used in annotations. They are building blocks for creating generic types.

class typing.Generic

Abstract base class for generic types.

A generic type is typically declared by inheriting from an instantiation of this class with one or more type variables. For

example, a generic mapping type might be defined as:

```
class Mapping(Generic[KT, VT]):
    def __getitem__(self, key: KT) -> VT:
        ...
        # Etc.
```

This class can then be used as follows:

```
X = TypeVar('X')
Y = TypeVar('Y')

def lookup_name(mapping: Mapping[X, Y], key: X, def
    try:
        return mapping[key]
    except KeyError:
        return default
```

class typing.TypeVar

Type variable.

Usage:

```
T = TypeVar('T')  # Can be anything
S = TypeVar('S', bound=str)  # Can be any subtype o
A = TypeVar('A', str, bytes)  # Must be exactly str
```

Type variables exist primarily for the benefit of static type checkers. They serve as the parameters for generic types as well as for generic function definitions. See **Generic** for more information on generic types. Generic functions work as follows:

```
def repeat(x: T, n: int) -> Sequence[T]:
    """Return a list containing n references to x."
    return [x]*n

def print_capitalized(x: S) -> S:
    """Print x capitalized, and return x."""
```

```
    print(x.capitalize())
    return x

def concatenate(x: A, y: A) -> A:
    """Add two strings or bytes objects together."""
    return x + y
```

Note that type variables can be *bound*, *constrained*, or neither, but cannot be both bound *and* constrained.

Bound type variables and constrained type variables have different semantics in several important ways. Using a *bound* type variable means that the `TypeVar` will be solved using the most specific type possible:

```
x = print_capitalized('a string')
reveal_type(x)  # revealed type is str

class StringSubclass(str):
    pass

y = print_capitalized(StringSubclass('another strin
reveal_type(y)  # revealed type is StringSubclass

z = print_capitalized(45)  # error: int is not a su
```

Type variables can be bound to concrete types, abstract types (ABCs or protocols), and even unions of types:

```
U = TypeVar('U', bound=str|bytes)  # Can be any sub
V = TypeVar('V', bound=SupportsAbs)  # Can be anyth
```

Using a *constrained* type variable, however, means that the `TypeVar` can only ever be solved as being exactly one of the constraints given:

```
a = concatenate('one', 'two')
reveal_type(a)  # revealed type is str
```

```
b = concatenate(StringSubclass('one'), StringSubcla
reveal_type(b)  # revealed type is str, despite Str

c = concatenate('one', b'two')  # error: type varia
```

At runtime, `isinstance(x, T)` will raise **`TypeError`**. In general, **`isinstance()`** and **`issubclass()`** should not be used with types.

Type variables may be marked covariant or contravariant by passing `covariant=True` or `contravariant=True`. See **PEP 484** [https://peps.python.org/pep-0484/] for more details. By default, type variables are invariant.

class typing.TypeVarTuple

Type variable tuple. A specialized form of **`type variable`** that enables *variadic* generics.

A normal type variable enables parameterization with a single type. A type variable tuple, in contrast, allows parameterization with an *arbitrary* number of types by acting like an *arbitrary* number of type variables wrapped in a tuple. For example:

```
T = TypeVar('T')
Ts = TypeVarTuple('Ts')

def move_first_element_to_last(tup: tuple[T, *Ts])
    return (*tup[1:], tup[0])

# T is bound to int, Ts is bound to ()
# Return value is (1,), which has type tuple[int]
move_first_element_to_last(tup=(1,))

# T is bound to int, Ts is bound to (str,)
# Return value is ('spam', 1), which has type tuple
move_first_element_to_last(tup=(1, 'spam'))

# T is bound to int, Ts is bound to (str, float)
```

```
# Return value is ('spam', 3.0, 1), which has type
move_first_element_to_last(tup=(1, 'spam', 3.0))

# This fails to type check (and fails at runtime)
# because tuple[()] is not compatible with tuple[T,
# (at least one element is required)
move_first_element_to_last(tup=())
```

Note the use of the unpacking operator `*` in `tuple[T, *Ts]`. Conceptually, you can think of `Ts` as a tuple of type variables `(T1, T2, ...)`. `tuple[T, *Ts]` would then become `tuple[T, *(T1, T2, ...)]`, which is equivalent to `tuple[T, T1, T2, ...]`. (Note that in older versions of Python, you might see this written using **`Unpack`** instead, as `Unpack[Ts]`.)

Type variable tuples must *always* be unpacked. This helps distinguish type variable tuples from normal type variables:

```
x: Ts          # Not valid
x: tuple[Ts]   # Not valid
x: tuple[*Ts]  # The correct way to to do it
```

Type variable tuples can be used in the same contexts as normal type variables. For example, in class definitions, arguments, and return types:

```
Shape = TypeVarTuple('Shape')
class Array(Generic[*Shape]):
    def __getitem__(self, key: tuple[*Shape]) -> fl
    def __abs__(self) -> "Array[*Shape]": ...
    def get_shape(self) -> tuple[*Shape]: ...
```

Type variable tuples can be happily combined with normal type variables:

```
DType = TypeVar('DType')

class Array(Generic[DType, *Shape]):  # This is fin
    pass
```

```
class Array2(Generic[*Shape, DType]):  # This would
    pass

float_array_1d: Array[float, Height] = Array()
int_array_2d: Array[int, Height, Width] = Array()
```

However, note that at most one type variable tuple may appear in a single list of type arguments or type parameters:

```
x: tuple[*Ts, *Ts]                          # Not valid
class Array(Generic[*Shape, *Shape]):  # Not valid
    pass
```

Finally, an unpacked type variable tuple can be used as the type annotation of `*args`:

```
def call_soon(
        callback: Callable[[*Ts], None],
        *args: *Ts
) -> None:
    ...
    callback(*args)
```

In contrast to non-unpacked annotations of `*args` - e.g. `*args: int`, which would specify that *all* arguments are `int` - `*args: *Ts` enables reference to the types of the *individual* arguments in `*args`. Here, this allows us to ensure the types of the `*args` passed to `call_soon` match the types of the (positional) arguments of `callback`.

See **PEP 646** [https://peps.python.org/pep-0646/] for more details on type variable tuples.

New in version 3.11.

typing.Unpack

A typing operator that conceptually marks an object as having been unpacked. For example, using the unpack operator `*` on a **`type variable tuple`** is equivalent to

using `Unpack` to mark the type variable tuple as having been unpacked:

```
Ts = TypeVarTuple('Ts')
tup: tuple[*Ts]
# Effectively does:
tup: tuple[Unpack[Ts]]
```

In fact, `Unpack` can be used interchangeably with `*` in the context of types. You might see `Unpack` being used explicitly in older versions of Python, where `*` couldn't be used in certain places:

```
# In older versions of Python, TypeVarTuple and Unp
# are located in the `typing_extensions` backports
from typing_extensions import TypeVarTuple, Unpack

Ts = TypeVarTuple('Ts')
tup: tuple[*Ts]          # Syntax error on Python <=
tup: tuple[Unpack[Ts]]   # Semantically equivalent,
```

New in version 3.11.

class typing.ParamSpec(*name*, *, *bound*=*None*, *covariant*=*False*, *contravariant*=*False*)

Parameter specification variable. A specialized version of **type variables**.

Usage:

```
P = ParamSpec('P')
```

Parameter specification variables exist primarily for the benefit of static type checkers. They are used to forward the parameter types of one callable to another callable – a pattern commonly found in higher order functions and decorators. They are only valid when used in `Concatenate`, or as the first argument to `Callable`, or as parameters for user-defined Generics. See **`Generic`** for more information on generic types.

For example, to add basic logging to a function, one can create a decorator `add_logging` to log function calls. The parameter specification variable tells the type checker that the callable passed into the decorator and the new callable returned by it have inter-dependent type parameters:

```
from collections.abc import Callable
from typing import TypeVar, ParamSpec
import logging

T = TypeVar('T')
P = ParamSpec('P')

def add_logging(f: Callable[P, T]) -> Callable[P, T
    '''A type-safe decorator to add logging to a fu
    def inner(*args: P.args, **kwargs: P.kwargs) ->
        logging.info(f'{f.__name__} was called')
        return f(*args, **kwargs)
    return inner

@add_logging
def add_two(x: float, y: float) -> float:
    '''Add two numbers together.'''
    return x + y
```

Without `ParamSpec`, the simplest way to annotate this previously was to use a **`TypeVar`** with bound `Callable[..., Any]`. However this causes two problems:

1. The type checker can't type check the `inner` function because `*args` and `**kwargs` have to be typed **`Any`**.
2. **`cast()`** may be required in the body of the `add_logging` decorator when returning the `inner` function, or the static type checker must be told to ignore the `return inner`.

args

kwargs

Since `ParamSpec` captures both positional and

keyword parameters, `P.args` and `P.kwargs` can be used to split a `ParamSpec` into its components. `P.args` represents the tuple of positional parameters in a given call and should only be used to annotate `*args`. `P.kwargs` represents the mapping of keyword parameters to their values in a given call, and should be only be used to annotate `**kwargs`. Both attributes require the annotated parameter to be in scope. At runtime, `P.args` and `P.kwargs` are instances respectively of **`ParamSpecArgs`** and **`ParamSpecKwargs`**.

Parameter specification variables created with `covariant=True` or `contravariant=True` can be used to declare covariant or contravariant generic types. The `bound` argument is also accepted, similar to **`TypeVar`**. However the actual semantics of these keywords are yet to be decided.

New in version 3.10.

Note

Only parameter specification variables defined in global scope can be pickled.

See also

- **PEP 612** [https://peps.python.org/pep-0612/] – Parameter Specification Variables (the PEP which introduced `ParamSpec` and `Concatenate`).
- **`Callable`** and **`Concatenate`**.

typing.ParamSpecArgs

typing.ParamSpecKwargs

Arguments and keyword arguments attributes of a **`ParamSpec`**. The `P.args` attribute of a `ParamSpec` is an

instance of `ParamSpecArgs`, and `P.kwargs` is an instance of `ParamSpecKwargs`. They are intended for runtime introspection and have no special meaning to static type checkers.

Calling **`get_origin()`** on either of these objects will return the original `ParamSpec`:

```
P = ParamSpec("P")
get_origin(P.args)  # returns P
get_origin(P.kwargs)  # returns P
```

New in version 3.10.

typing.AnyStr

`AnyStr` is a **`constrained type variable`** defined as `AnyStr = TypeVar('AnyStr', str, bytes)`.

It is meant to be used for functions that may accept any kind of string without allowing different kinds of strings to mix. For example:

```
def concat(a: AnyStr, b: AnyStr) -> AnyStr:
    return a + b

concat(u"foo", u"bar")  # Ok, output has type 'unic
concat(b"foo", b"bar")  # Ok, output has type 'byte
concat(u"foo", b"bar")  # Error, cannot mix unicode
```

class typing.Protocol(*Generic*)

Base class for protocol classes. Protocol classes are defined like this:

```
class Proto(Protocol):
    def meth(self) -> int:
        ...
```

Such classes are primarily used with static type checkers that recognize structural subtyping (static duck-typing), for example:

```
class C:
    def meth(self) -> int:
        return 0

def func(x: Proto) -> int:
    return x.meth()

func(C())  # Passes static type check
```

See **PEP 544** [https://peps.python.org/pep-0544/] for more details. Protocol classes decorated with **runtime_checkable()** (described later) act as simple-minded runtime protocols that check only the presence of given attributes, ignoring their type signatures.

Protocol classes can be generic, for example:

```
class GenProto(Protocol[T]):
    def meth(self) -> T:
        ...
```

New in version 3.8.

@typing.runtime_checkable

Mark a protocol class as a runtime protocol.

Such a protocol can be used with **isinstance()** and **issubclass()**. This raises **TypeError** when applied to a non-protocol class. This allows a simple-minded structural check, very similar to “one trick ponies” in **collections.abc** such as **Iterable**. For example:

```
@runtime_checkable
class Closable(Protocol):
    def close(self): ...

assert isinstance(open('/some/file'), Closable)
```

Note

runtime_checkable() will check only the presence of the required methods, not their type signatures. For example, **ssl.SSLObject** is a class, therefore it passes an **issubclass()** check against **Callable**. However, the **ssl.SSLObject.__init__()** method exists only to raise a **TypeError** with a more informative message, therefore making it impossible to call (instantiate) **ssl.SSLObject**.

New in version 3.8.

Other special directives

These are not used in annotations. They are building blocks for declaring types.

class typing.NamedTuple

Typed version of **collections.namedtuple()**.

Usage:

```
class Employee(NamedTuple):
    name: str
    id: int
```

This is equivalent to:

```
Employee = collections.namedtuple('Employee', ['nam
```

To give a field a default value, you can assign to it in the class body:

```
class Employee(NamedTuple):
    name: str
    id: int = 3

employee = Employee('Guido')
assert employee.id == 3
```

Fields with a default value must come after any fields without

a default.

The resulting class has an extra attribute `__annotations__` giving a dict that maps the field names to the field types. (The field names are in the `_fields` attribute and the default values are in the `_field_defaults` attribute, both of which are part of the **`namedtuple()`** API.)

`NamedTuple` subclasses can also have docstrings and methods:

```
class Employee(NamedTuple):
    """Represents an employee."""
    name: str
    id: int = 3

    def __repr__(self) -> str:
        return f'<Employee {self.name}, id={self.id
```

`NamedTuple` subclasses can be generic:

```
class Group(NamedTuple, Generic[T]):
    key: T
    group: list[T]
```

Backward-compatible usage:

```
Employee = NamedTuple('Employee', [('name', str), (
```

Changed in version 3.6: Added support for **PEP 526** [https://peps.python.org/pep-0526/] variable annotation syntax.

Changed in version 3.6.1: Added support for default values, methods, and docstrings.

Changed in version 3.8: The `_field_types` and `__annotations__` attributes are now regular dictionaries instead of instances of `OrderedDict`.

Changed in version 3.9: Removed the `_field_types` attribute in favor of the more standard `__annotations__`

attribute which has the same information.

Changed in version 3.11: Added support for generic namedtuples.

class typing.NewType(*name*, *tp*)

A helper class to indicate a distinct type to a typechecker, see NewType. At runtime it returns an object that returns its argument when called. Usage:

```
UserId = NewType('UserId', int)
first_user = UserId(1)
```

New in version 3.5.2.

Changed in version 3.10: `NewType` is now a class rather than a function.

class typing.TypedDict(*dict*)

Special construct to add type hints to a dictionary. At runtime it is a plain **`dict`**.

`TypedDict` declares a dictionary type that expects all of its instances to have a certain set of keys, where each key is associated with a value of a consistent type. This expectation is not checked at runtime but is only enforced by type checkers. Usage:

```
class Point2D(TypedDict):
    x: int
    y: int
    label: str

a: Point2D = {'x': 1, 'y': 2, 'label': 'good'}  # O
b: Point2D = {'z': 3, 'label': 'bad'}           # F

assert Point2D(x=1, y=2, label='first') == dict(x=1
```

To allow using this feature with older versions of Python that do not support **PEP 526** [https://peps.python.org/pep-0526/],

`TypedDict` supports two additional equivalent syntactic forms:

- Using a literal **`dict`** as the second argument:

  ```
  Point2D = TypedDict('Point2D', {'x': int, 'y':
  ```

- Using keyword arguments:

  ```
  Point2D = TypedDict('Point2D', x=int, y=int, la
  ```

Deprecated since version 3.11, will be removed in version 3.13: The keyword-argument syntax is deprecated in 3.11 and will be removed in 3.13. It may also be unsupported by static type checkers.

The functional syntax should also be used when any of the keys are not valid identifiers, for example because they are keywords or contain hyphens. Example:

```
# raises SyntaxError
class Point2D(TypedDict):
    in: int  # 'in' is a keyword
    x-y: int  # name with hyphens

# OK, functional syntax
Point2D = TypedDict('Point2D', {'in': int, 'x-y': i
```

By default, all keys must be present in a `TypedDict`. It is possible to mark individual keys as non-required using **`NotRequired`**:

```
class Point2D(TypedDict):
    x: int
    y: int
    label: NotRequired[str]

# Alternative syntax
Point2D = TypedDict('Point2D', {'x': int, 'y': int,
```

This means that a `Point2D TypedDict` can have the

`label` key omitted.

It is also possible to mark all keys as non-required by default by specifying a totality of `False`:

```
class Point2D(TypedDict, total=False):
    x: int
    y: int

# Alternative syntax
Point2D = TypedDict('Point2D', {'x': int, 'y': int}
```

This means that a `Point2D TypedDict` can have any of the keys omitted. A type checker is only expected to support a literal `False` or `True` as the value of the `total` argument. `True` is the default, and makes all items defined in the class body required.

Individual keys of a `total=False TypedDict` can be marked as required using **`Required`**:

```
class Point2D(TypedDict, total=False):
    x: Required[int]
    y: Required[int]
    label: str

# Alternative syntax
Point2D = TypedDict('Point2D', {
    'x': Required[int],
    'y': Required[int],
    'label': str
}, total=False)
```

It is possible for a `TypedDict` type to inherit from one or more other `TypedDict` types using the class-based syntax. Usage:

```
class Point3D(Point2D):
    z: int
```

`Point3D` has three items: `x`, `y` and `z`. It is equivalent to this definition:

```
class Point3D(TypedDict):
    x: int
    y: int
    z: int
```

A `TypedDict` cannot inherit from a non-`TypedDict` class, except for **`Generic`**. For example:

```
class X(TypedDict):
    x: int

class Y(TypedDict):
    y: int

class Z(object): pass  # A non-TypedDict class

class XY(X, Y): pass  # OK

class XZ(X, Z): pass  # raises TypeError

T = TypeVar('T')
class XT(X, Generic[T]): pass  # raises TypeError
```

A `TypedDict` can be generic:

```
class Group(TypedDict, Generic[T]):
    key: T
    group: list[T]
```

A `TypedDict` can be introspected via annotations dicts (see Annotations Best Practices for more information on annotations best practices), **`__total__`**, **`__required_keys__`**, and **`__optional_keys__`**.

total

`Point2D.__total__` gives the value of the `total` argument. Example:

```
>>> from typing import TypedDict
>>> class Point2D(TypedDict): pass
>>> Point2D.__total__
True
>>> class Point2D(TypedDict, total=False): pass
>>> Point2D.__total__
False
>>> class Point3D(Point2D): pass
>>> Point3D.__total__
True
```

_required_keys_

New in version 3.9.

_optional_keys_

`Point2D.__required_keys__` and `Point2D.__optional_keys__` return **`frozenset`** objects containing required and non-required keys, respectively.

Keys marked with **`Required`** will always appear in `__required_keys__` and keys marked with **`NotRequired`** will always appear in `__optional_keys__`.

For backwards compatibility with Python 3.10 and below, it is also possible to use inheritance to declare both required and non-required keys in the same `TypedDict` . This is done by declaring a `TypedDict` with one value for the `total` argument and then inheriting from it in another `TypedDict` with a different value for `total`:

```
>>> class Point2D(TypedDict, total=False):
...     x: int
...     y: int
...
>>> class Point3D(Point2D):
...     z: int
```

```
...
>>> Point3D.__required_keys__ == frozenset({'z'
True
>>> Point3D.__optional_keys__ == frozenset({'x'
True
```

New in version 3.9.

See **PEP 589** [https://peps.python.org/pep-0589/] for more examples and detailed rules of using `TypedDict`.

New in version 3.8.

Changed in version 3.11: Added support for marking individual keys as **`Required`** or **`NotRequired`**. See **PEP 655** [https://peps.python.org/pep-0655/].

Changed in version 3.11: Added support for generic `TypedDict`s.

Generic concrete collections

Corresponding to built-in types

class typing.Dict(*dict, MutableMapping[KT, VT]*)

A generic version of **`dict`**. Useful for annotating return types. To annotate arguments it is preferred to use an abstract collection type such as **`Mapping`**.

This type can be used as follows:

```
def count_words(text: str) -> Dict[str, int]:
    ...
```

Deprecated since version 3.9: **`builtins.dict`** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.List(*list, MutableSequence[T]*)

Generic version of **list**. Useful for annotating return types. To annotate arguments it is preferred to use an abstract collection type such as **Sequence** or **Iterable**.

This type may be used as follows:

```
T = TypeVar('T', int, float)

def vec2(x: T, y: T) -> List[T]:
    return [x, y]

def keep_positives(vector: Sequence[T]) -> List[T]:
    return [item for item in vector if item > 0]
```

Deprecated since version 3.9: **builtins.list** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Set(*set, MutableSet[T]*)

A generic version of **builtins.set**. Useful for annotating return types. To annotate arguments it is preferred to use an abstract collection type such as **AbstractSet**.

Deprecated since version 3.9: **builtins.set** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.FrozenSet(*frozenset, AbstractSet[T_co]*)

A generic version of **builtins.frozenset**.

Deprecated since version 3.9: **builtins.frozenset** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

Note

Tuple is a special form.

Corresponding to types in `collections`

class typing.DefaultDict(*collections.defaultdict, MutableMapping[KT, VT]*)

A generic version of `collections.defaultdict`.

New in version 3.5.2.

Deprecated since version 3.9: `collections.defaultdict` now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.OrderedDict(*collections.OrderedDict, MutableMapping[KT, VT]*)

A generic version of `collections.OrderedDict`.

New in version 3.7.2.

Deprecated since version 3.9: `collections.OrderedDict` now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.ChainMap(*collections.ChainMap, MutableMapping[KT, VT]*)

A generic version of `collections.ChainMap`.

New in version 3.5.4.

New in version 3.6.1.

Deprecated since version 3.9: `collections.ChainMap` now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Counter(*collections.Counter, Dict[T, int]*)

A generic version of `collections.Counter`.

New in version 3.5.4.

New in version 3.6.1.

Deprecated since version 3.9: `collections.Counter` now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Deque(*deque, MutableSequence[T]*)

A generic version of `collections.deque`.

New in version 3.5.4.

New in version 3.6.1.

Deprecated since version 3.9: `collections.deque` now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

Other concrete types

class typing.IO
class typing.TextIO
class typing.BinaryIO

Generic type `IO[AnyStr]` and its subclasses `TextIO(IO[str])` and `BinaryIO(IO[bytes])` represent the types of I/O streams such as returned by `open()`.

Deprecated since version 3.8, will be removed in version 3.13: The `typing.io` namespace is deprecated and will be removed. These types should be directly imported from `typing` instead.

class typing.Pattern
class typing.Match

These type aliases correspond to the return types from `re.compile()` and `re.match()`. These types (and the corresponding functions) are generic in `AnyStr` and can be made specific by writing `Pattern[str]`, `Pattern[bytes]`, `Match[str]`, or `Match[bytes]`.

Deprecated since version 3.8, will be removed in version 3.13:

The `typing.re` namespace is deprecated and will be removed. These types should be directly imported from `typing` instead.

Deprecated since version 3.9: Classes `Pattern` and `Match` from **`re`** now support `[]`. See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Text

`Text` is an alias for `str`. It is provided to supply a forward compatible path for Python 2 code: in Python 2, `Text` is an alias for `unicode`.

Use `Text` to indicate that a value must contain a unicode string in a manner that is compatible with both Python 2 and Python 3:

```
def add_unicode_checkmark(text: Text) -> Text:
    return text + u' \u2713'
```

New in version 3.5.2.

Deprecated since version 3.11: Python 2 is no longer supported, and most type checkers also no longer support type checking Python 2 code. Removal of the alias is not currently planned, but users are encouraged to use **`str`** instead of `Text` wherever possible.

Abstract Base Classes

Corresponding to collections in **`collections.abc`**

class typing.AbstractSet(*Collection[T_co]*)

A generic version of **`collections.abc.Set`**.

Deprecated since version 3.9: **`collections.abc.Set`** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.ByteString(*Sequence[int]*)

A generic version of **collections.abc.ByteString**.

This type represents the types **bytes**, **bytearray**, and **memoryview** of byte sequences.

As a shorthand for this type, **bytes** can be used to annotate arguments of any of the types mentioned above.

Deprecated since version 3.9:
collections.abc.ByteString now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Collection(*Sized, Iterable[T_co], Container[T_co]*)

A generic version of **collections.abc.Collection**

New in version 3.6.0.

Deprecated since version 3.9:
collections.abc.Collection now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Container(*Generic[T_co]*)

A generic version of **collections.abc.Container**.

Deprecated since version 3.9:
collections.abc.Container now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.ItemsView(*MappingView, AbstractSet[tuple[KT_co, VT_co]]*)

A generic version of **collections.abc.ItemsView**.

Deprecated since version 3.9:
collections.abc.ItemsView now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic

Alias Type.

class typing.KeysView(*MappingView, AbstractSet[KT_co]*)

A generic version of **collections.abc.KeysView**.

Deprecated since version 3.9: **collections.abc.KeysView** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Mapping(*Collection[KT], Generic[KT, VT_co]*)

A generic version of **collections.abc.Mapping**. This type can be used as follows:

```
def get_position_in_index(word_list: Mapping[str, i
    return word_list[word]
```

Deprecated since version 3.9: **collections.abc.Mapping** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.MappingView(*Sized*)

A generic version of **collections.abc.MappingView**.

Deprecated since version 3.9: **collections.abc.MappingView** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.MutableMapping(*Mapping[KT, VT]*)

A generic version of **collections.abc.MutableMapping**.

Deprecated since version 3.9: **collections.abc.MutableMapping** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.MutableSequence(*Sequence[T]*)

A generic version of **collections.abc.MutableSequence**.

Deprecated since version 3.9: **collections.abc.MutableSequence** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.MutableSet(*AbstractSet[T]*)

A generic version of **collections.abc.MutableSet**.

Deprecated since version 3.9: **collections.abc.MutableSet** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Sequence(*Reversible[T_co], Collection[T_co]*)

A generic version of **collections.abc.Sequence**.

Deprecated since version 3.9: **collections.abc.Sequence** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.ValuesView(*MappingView, Collection[_VT_co]*)

A generic version of **collections.abc.ValuesView**.

Deprecated since version 3.9: **collections.abc.ValuesView** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

Corresponding to other types in collections.abc

class typing.Iterable(*Generic[T_co]*)

A generic version of **collections.abc.Iterable**.

Deprecated since version 3.9: **collections.abc.Iterable** now supports subscripting ([]). See **PEP 585** [https://

peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Iterator(*Iterable[T_co]*)

A generic version of **collections.abc.Iterator**.

Deprecated since version 3.9: **collections.abc.Iterator** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Generator(*Iterator[T_co], Generic[T_co, T_contra, V_co]*)

A generator can be annotated by the generic type `Generator[YieldType, SendType, ReturnType]`. For example:

```
def echo_round() -> Generator[int, float, str]:
    sent = yield 0
    while sent >= 0:
        sent = yield round(sent)
    return 'Done'
```

Note that unlike many other generics in the typing module, the `SendType` of **Generator** behaves contravariantly, not covariantly or invariantly.

If your generator will only yield values, set the `SendType` and `ReturnType` to `None`:

```
def infinite_stream(start: int) -> Generator[int, N
    while True:
        yield start
        start += 1
```

Alternatively, annotate your generator as having a return type of either `Iterable[YieldType]` or `Iterator[YieldType]`:

```
def infinite_stream(start: int) -> Iterator[int]:
    while True:
        yield start
```

```
            start += 1
```

Deprecated since version 3.9:
collections.abc.Generator now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Hashable
An alias to **collections.abc.Hashable**.

class typing.Reversible(*Iterable[T_co]*)
A generic version of **collections.abc.Reversible**.

Deprecated since version 3.9:
collections.abc.Reversible now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Sized
An alias to **collections.abc.Sized**.

Asynchronous programming

class typing.Coroutine(*Awaitable[V_co], Generic[T_co, T_contra, V_co]*)
A generic version of **collections.abc.Coroutine**. The variance and order of type variables correspond to those of **Generator**, for example:

```
from collections.abc import Coroutine
c: Coroutine[list[str], str, int]  # Some coroutine
x = c.send('hi')                   # Inferred type
async def bar() -> None:
    y = await c                    # Inferred type
```

New in version 3.5.3.

Deprecated since version 3.9:

collections.abc.Coroutine now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.AsyncGenerator(*AsyncIterator[T_co], Generic[T_co, T_contra]*)

An async generator can be annotated by the generic type `AsyncGenerator[YieldType, SendType]`. For example:

```
async def echo_round() -> AsyncGenerator[int, float
    sent = yield 0
    while sent >= 0.0:
        rounded = await round(sent)
        sent = yield rounded
```

Unlike normal generators, async generators cannot return a value, so there is no `ReturnType` type parameter. As with **Generator**, the `SendType` behaves contravariantly.

If your generator will only yield values, set the `SendType` to `None`:

```
async def infinite_stream(start: int) -> AsyncGener
    while True:
        yield start
        start = await increment(start)
```

Alternatively, annotate your generator as having a return type of either `AsyncIterable[YieldType]` or `AsyncIterator[YieldType]`:

```
async def infinite_stream(start: int) -> AsyncItera
    while True:
        yield start
        start = await increment(start)
```

New in version 3.6.1.

Deprecated since version 3.9:
collections.abc.AsyncGenerator now supports

subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.AsyncIterable(*Generic[T_co]*)

A generic version of **collections.abc.AsyncIterable**.

New in version 3.5.2.

Deprecated since version 3.9: **collections.abc.AsyncIterable** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.AsyncIterator(*AsyncIterable[T_co]*)

A generic version of **collections.abc.AsyncIterator**.

New in version 3.5.2.

Deprecated since version 3.9: **collections.abc.AsyncIterator** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.Awaitable(*Generic[T_co]*)

A generic version of **collections.abc.Awaitable**.

New in version 3.5.2.

Deprecated since version 3.9: **collections.abc.Awaitable** now supports subscripting ([]). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

Context manager types

class typing.ContextManager(*Generic[T_co]*)

A generic version of **contextlib.AbstractContextManager**.

New in version 3.5.4.

New in version 3.6.0.

Deprecated since version 3.9: **contextlib.AbstractContextManager** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

class typing.AsyncContextManager(*Generic[T_co]*)

A generic version of **contextlib.AbstractAsyncContextManager**.

New in version 3.5.4.

New in version 3.6.2.

Deprecated since version 3.9: **contextlib.AbstractAsyncContextManager** now supports subscripting (`[]`). See **PEP 585** [https://peps.python.org/pep-0585/] and Generic Alias Type.

Protocols

These protocols are decorated with **runtime_checkable()**.

class typing.SupportsAbs

An ABC with one abstract method `__abs__` that is covariant in its return type.

class typing.SupportsBytes

An ABC with one abstract method `__bytes__`.

class typing.SupportsComplex

An ABC with one abstract method `__complex__`.

class typing.SupportsFloat

An ABC with one abstract method `__float__`.

class typing.SupportsIndex

An ABC with one abstract method `__index__`.

New in version 3.8.

class typing.SupportsInt

An ABC with one abstract method `__int__`.

class typing.SupportsRound

An ABC with one abstract method `__round__` that is covariant in its return type.

Functions and decorators

typing.cast(*typ*, *val*)

Cast a value to a type.

This returns the value unchanged. To the type checker this signals that the return value has the designated type, but at runtime we intentionally don't check anything (we want this to be as fast as possible).

typing.assert_type(*val*, *typ*, */*)

Ask a static type checker to confirm that *val* has an inferred type of *typ*.

When the type checker encounters a call to `assert_type()`, it emits an error if the value is not of the specified type:

```
def greet(name: str) -> None:
    assert_type(name, str)  # OK, inferred type of
    assert_type(name, int)  # type checker error
```

At runtime this returns the first argument unchanged with no side effects.

This function is useful for ensuring the type checker's understanding of a script is in line with the developer's

intentions:

```
def complex_function(arg: object):
    # Do some complex type-narrowing logic,
    # after which we hope the inferred type will be
    ...
    # Test whether the type checker correctly under
    assert_type(arg, int)
```

New in version 3.11.

typing.assert_never(*arg*, */*)

Ask a static type checker to confirm that a line of code is unreachable.

Example:

```
def int_or_str(arg: int | str) -> None:
    match arg:
        case int():
            print("It's an int")
        case str():
            print("It's a str")
        case _ as unreachable:
            assert_never(unreachable)
```

Here, the annotations allow the type checker to infer that the last case can never execute, because `arg` is either an **`int`** or a **`str`**, and both options are covered by earlier cases. If a type checker finds that a call to `assert_never()` is reachable, it will emit an error. For example, if the type annotation for `arg` was instead `int | str | float`, the type checker would emit an error pointing out that `unreachable` is of type **`float`**. For a call to `assert_never` to pass type checking, the inferred type of the argument passed in must be the bottom type, **`Never`**, and nothing else.

At runtime, this throws an exception when called.

See also

Unreachable Code and Exhaustiveness Checking [https://typing.readthedocs.io/en/latest/source/unreachable.html] has more information about exhaustiveness checking with static typing.

New in version 3.11.

typing.reveal_type(*obj*, */*)

Reveal the inferred static type of an expression.

When a static type checker encounters a call to this function, it emits a diagnostic with the type of the argument. For example:

```
x: int = 1
reveal_type(x)  # Revealed type is "builtins.int"
```

This can be useful when you want to debug how your type checker handles a particular piece of code.

The function returns its argument unchanged, which allows using it within an expression:

```
x = reveal_type(1)  # Revealed type is "builtins.in
```

Most type checkers support `reveal_type()` anywhere, even if the name is not imported from `typing`. Importing the name from `typing` allows your code to run without runtime errors and communicates intent more clearly.

At runtime, this function prints the runtime type of its argument to stderr and returns it unchanged:

```
x = reveal_type(1)  # prints "Runtime type is int"
print(x)  # prints "1"
```

New in version 3.11.

@typing.dataclass_transform

dataclass_transform may be used to decorate a class, metaclass, or a function that is itself a decorator. The presence of `@dataclass_transform()` tells a static type checker that the decorated object performs runtime "magic" that transforms a class, giving it **dataclasses.dataclass()**-like behaviors.

Example usage with a decorator function:

```
T = TypeVar("T")

@dataclass_transform()
def create_model(cls: type[T]) -> type[T]:
    ...
    return cls

@create_model
class CustomerModel:
    id: int
    name: str
```

On a base class:

```
@dataclass_transform()
class ModelBase: ...

class CustomerModel(ModelBase):
    id: int
    name: str
```

On a metaclass:

```
@dataclass_transform()
class ModelMeta(type): ...

class ModelBase(metaclass=ModelMeta): ...

class CustomerModel(ModelBase):
    id: int
    name: str
```

The `CustomerModel` classes defined above will be treated by type checkers similarly to classes created with **`@dataclasses.dataclass`**. For example, type checkers will assume these classes have `__init__` methods that accept `id` and `name`.

The decorated class, metaclass, or function may accept the following bool arguments which type checkers will assume have the same effect as they would have on the **`@dataclasses.dataclass`** decorator: `init`, `eq`, `order`, `unsafe_hash`, `frozen`, `match_args`, `kw_only`, and `slots`. It must be possible for the value of these arguments (`True` or `False`) to be statically evaluated.

The arguments to the `dataclass_transform` decorator can be used to customize the default behaviors of the decorated class, metaclass, or function:

- `eq_default` indicates whether the `eq` parameter is assumed to be `True` or `False` if it is omitted by the caller.
- `order_default` indicates whether the `order` parameter is assumed to be True or False if it is omitted by the caller.
- `kw_only_default` indicates whether the `kw_only` parameter is assumed to be True or False if it is omitted by the caller.
- `field_specifiers` specifies a static list of supported classes or functions that describe fields, similar to `dataclasses.field()`.
- Arbitrary other keyword arguments are accepted in order to allow for possible future extensions.

Type checkers recognize the following optional arguments on field specifiers:

- `init` indicates whether the field should be included in the synthesized `__init__` method. If unspecified, `init` defaults to `True`.
- `default` provides the default value for the field.
- `default_factory` provides a runtime callback that

returns the default value for the field. If neither `default` nor `default_factory` are specified, the field is assumed to have no default value and must be provided a value when the class is instantiated.

- `factory` is an alias for `default_factory`.
- `kw_only` indicates whether the field should be marked as keyword-only. If `True`, the field will be keyword-only. If `False`, it will not be keyword-only. If unspecified, the value of the `kw_only` parameter on the object decorated with `dataclass_transform` will be used, or if that is unspecified, the value of `kw_only_default` on `dataclass_transform` will be used.
- `alias` provides an alternative name for the field. This alternative name is used in the synthesized `__init__` method.

At runtime, this decorator records its arguments in the `__dataclass_transform__` attribute on the decorated object. It has no other runtime effect.

See **PEP 681** [https://peps.python.org/pep-0681/] for more details.

New in version 3.11.

@typing.overload

The `@overload` decorator allows describing functions and methods that support multiple different combinations of argument types. A series of `@overload`-decorated definitions must be followed by exactly one non-`@overload`-decorated definition (for the same function/method). The `@overload`-decorated definitions are for the benefit of the type checker only, since they will be overwritten by the non-`@overload`-decorated definition, while the latter is used at runtime but should be ignored by a type checker. At runtime, calling a `@overload`-decorated function directly will raise **`NotImplementedError`**. An example of overload that gives a more precise type than can be expressed using a union or a type variable:

```
@overload
def process(response: None) -> None:
    ...
@overload
def process(response: int) -> tuple[int, str]:
    ...
@overload
def process(response: bytes) -> str:
    ...
def process(response):
    <actual implementation>
```

See **PEP 484** [https://peps.python.org/pep-0484/] for more details and comparison with other typing semantics.

Changed in version 3.11: Overloaded functions can now be introspected at runtime using `get_overloads()`.

typing.get_overloads(*func*)

Return a sequence of `@overload`-decorated definitions for *func*. *func* is the function object for the implementation of the overloaded function. For example, given the definition of `process` in the documentation for `@overload`, `get_overloads(process)` will return a sequence of three function objects for the three defined overloads. If called on a function with no overloads, `get_overloads()` returns an empty sequence.

`get_overloads()` can be used for introspecting an overloaded function at runtime.

New in version 3.11.

typing.clear_overloads()

Clear all registered overloads in the internal registry. This can be used to reclaim the memory used by the registry.

New in version 3.11.

@typing.final

A decorator to indicate to type checkers that the decorated method cannot be overridden, and the decorated class cannot be subclassed. For example:

```
class Base:
    @final
    def done(self) -> None:
        ...
class Sub(Base):
    def done(self) -> None:  # Error reported by ty
        ...

@final
class Leaf:
    ...
class Other(Leaf):  # Error reported by type checke
    ...
```

There is no runtime checking of these properties. See **PEP 591** [https://peps.python.org/pep-0591/] for more details.

New in version 3.8.

Changed in version 3.11: The decorator will now set the `__final__` attribute to `True` on the decorated object. Thus, a check like `if getattr(obj, "__final__", False)` can be used at runtime to determine whether an object `obj` has been marked as final. If the decorated object does not support setting attributes, the decorator returns the object unchanged without raising an exception.

@typing.no_type_check

Decorator to indicate that annotations are not type hints.

This works as class or function decorator. With a class, it applies recursively to all methods and classes defined in that class (but not to methods defined in its superclasses or subclasses).

This mutates the function(s) in place.

@typing.no_type_check_decorator

Decorator to give another decorator the **no_type_check()** effect.

This wraps the decorator with something that wraps the decorated function in **no_type_check()**.

@typing.type_check_only

Decorator to mark a class or function to be unavailable at runtime.

This decorator is itself not available at runtime. It is mainly intended to mark classes that are defined in type stub files if an implementation returns an instance of a private class:

```
@type_check_only
class Response:  # private or not available at runt
    code: int
    def get_header(self, name: str) -> str: ...

def fetch_response() -> Response: ...
```

Note that returning instances of private classes is not recommended. It is usually preferable to make such classes public.

Introspection helpers

typing.get_type_hints(*obj*, *globalns=None*, *localns=None*, *include_extras=False*)

Return a dictionary containing type hints for a function, method, module or class object.

This is often the same as `obj.__annotations__`. In addition, forward references encoded as string literals are handled by evaluating them in `globals` and `locals` namespaces. For a class `C`, return a dictionary constructed by

merging all the `__annotations__` along `C.__mro__` in reverse order.

The function recursively replaces all `Annotated[T, ...]` with `T`, unless `include_extras` is set to `True` (see **`Annotated`** for more information). For example:

```
class Student(NamedTuple):
    name: Annotated[str, 'some marker']

get_type_hints(Student) == {'name': str}
get_type_hints(Student, include_extras=False) == {'
get_type_hints(Student, include_extras=True) == {
    'name': Annotated[str, 'some marker']
}
```

Note

`get_type_hints()` does not work with imported type aliases that include forward references. Enabling postponed evaluation of annotations (**PEP 563** [https://peps.python.org/pep-0563/]) may remove the need for most forward references.

Changed in version 3.9: Added `include_extras` parameter as part of **PEP 593** [https://peps.python.org/pep-0593/].

Changed in version 3.11: Previously, `Optional[t]` was added for function and method annotations if a default value equal to `None` was set. Now the annotation is returned unchanged.

typing.get_args(*tp*)

typing.get_origin(*tp*)

Provide basic introspection for generic types and special typing forms.

For a typing object of the form `X[Y, Z, ...]` these

functions return `X` and `(Y, Z, ...)`. If `X` is a generic alias for a builtin or `collections` class, it gets normalized to the original class. If `X` is a union or `Literal` contained in another generic type, the order of `(Y, Z, ...)` may be different from the order of the original arguments `[Y, Z, ...]` due to type caching. For unsupported objects return `None` and `()` correspondingly. Examples:

```
assert get_origin(Dict[str, int]) is dict
assert get_args(Dict[int, str]) == (int, str)

assert get_origin(Union[int, str]) is Union
assert get_args(Union[int, str]) == (int, str)
```

New in version 3.8.

typing.is_typeddict(*tp*)

Check if a type is a `TypedDict`.

For example:

```
class Film(TypedDict):
    title: str
    year: int

is_typeddict(Film)  # => True
is_typeddict(list | str)  # => False
```

New in version 3.10.

class typing.ForwardRef

A class used for internal typing representation of string forward references. For example, `List["SomeClass"]` is implicitly transformed into `List[ForwardRef("SomeClass")]`. This class should not be instantiated by a user, but may be used by introspection tools.

Note

PEP 585 [https://peps.python.org/pep-0585/] generic types such as `list["SomeClass"]` will not be implicitly transformed into `list[ForwardRef("SomeClass")]` and thus will not automatically resolve to `list[SomeClass]`.

New in version 3.7.4.

Constant

typing.TYPE_CHECKING

A special constant that is assumed to be `True` by 3rd party static type checkers. It is `False` at runtime. Usage:

```
if TYPE_CHECKING:
    import expensive_mod

def fun(arg: 'expensive_mod.SomeType') -> None:
    local_var: expensive_mod.AnotherType = other_fu
```

The first type annotation must be enclosed in quotes, making it a "forward reference", to hide the `expensive_mod` reference from the interpreter runtime. Type annotations for local variables are not evaluated, so the second annotation does not need to be enclosed in quotes.

Note

If `from __future__ import annotations` is used, annotations are not evaluated at function definition time. Instead, they are stored as strings in `__annotations__`. This makes it unnecessary to use quotes around the annotation (see **PEP 563** [https://peps.python.org/pep-0563/]).

New in version 3.5.2.

Deprecation Timeline of Major Features

Certain features in `typing` are deprecated and may be removed in a future version of Python. The following table summarizes major deprecations for your convenience. This is subject to change, and not all deprecations are listed.

Feature	Deprecated in	Planned removal
`typing.io` and `typing.re` submodules	3.8	3.13
Aliases to built-in types, collections, and other types in `typing`	various	undecided
`typing.Text`	3.11	undecided

`pydoc` — Documentation generator and online help system

Source code: Lib/pydoc.py [https://github.com/python/cpython/tree/3.11/Lib/pydoc.py]

The `pydoc` module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a web browser, or saved to HTML files.

For modules, classes, functions and methods, the displayed documentation is derived from the docstring (i.e. the `__doc__` attribute) of the object, and recursively of its documentable members. If there is no docstring, `pydoc` tries to obtain a description from the block of comment lines just above the definition of the class, function or method in the source file, or at the top of the module (see `inspect.getcomments()`).

The built-in function `help()` invokes the online help system in the interactive interpreter, which uses `pydoc` to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running **pydoc** as a script at the operating system's command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the `sys` module, in a style similar to the manual pages shown by the Unix **man** command. The argument to **pydoc** can be the name of a function, module, or package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument

to **pydoc** looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

> **Note**
>
> In order to find objects and their documentation, **pydoc** imports the module(s) to be documented. Therefore, any code on module level will be executed on that occasion. Use an `if __name__ == '__main__':` guard to only execute code when a file is invoked as a script and not just imported.

When printing output to the console, **pydoc** attempts to paginate the output for easier reading. If the **PAGER** environment variable is set, **pydoc** will use its value as a pagination program.

Specifying a `-w` flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a `-k` flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix **man** command. The synopsis line of a module is the first line of its documentation string.

You can also use **pydoc** to start an HTTP server on the local machine that will serve documentation to visiting web browsers. **pydoc -p 1234** will start a HTTP server on port 1234, allowing you to browse the documentation at `http://localhost:1234/` in your preferred web browser. Specifying `0` as the port number will select an arbitrary unused port.

pydoc -n <**hostname**> will start the server listening at the given hostname. By default the hostname is 'localhost' but if you want the server to be reached from other machines, you may want to change the host name that the server responds to. During development this is especially useful if you want to run pydoc from within a container.

pydoc -b will start the server and additionally open a web browser to a module index page. Each served page has a navigation bar at the top where you can *Get* help on an individual item, *Search* all modules with a keyword in their synopsis line, and go to the *Module index*, *Topics* and *Keywords* pages.

When **pydoc** generates documentation, it uses the current environment and path to locate modules. Thus, invoking **pydoc spam** documents precisely the version of the module you would get if you started the Python interpreter and typed `import spam`.

Module docs for core modules are assumed to reside in `https://docs.python.org/X.Y/library/` where `X` and `Y` are the major and minor version numbers of the Python interpreter. This can be overridden by setting the **`PYTHONDOCS`** environment variable to a different URL or to a local directory containing the Library Reference Manual pages.

Changed in version 3.2: Added the `-b` option.

Changed in version 3.3: The `-g` command line option was removed.

Changed in version 3.4: **`pydoc`** now uses **`inspect.signature()`** rather than **`inspect.getfullargspec()`** to extract signature information from callables.

Changed in version 3.7: Added the `-n` option.

Python Development Mode

New in version 3.7.

The Python Development Mode introduces additional runtime checks that are too expensive to be enabled by default. It should not be more verbose than the default if the code is correct; new warnings are only emitted when an issue is detected.

It can be enabled using the **`-X dev`** command line option or by setting the **`PYTHONDEVMODE`** environment variable to `1`.

See also Python debug build.

Effects of the Python Development Mode

Enabling the Python Development Mode is similar to the following command, but with additional effects described below:

```
PYTHONMALLOC=debug PYTHONASYNCIODEBUG=1 python3 -W defau
```

Effects of the Python Development Mode:

- Add `default` warning filter. The following warnings are shown:
  - **`DeprecationWarning`**
  - **`ImportWarning`**
  - **`PendingDeprecationWarning`**
  - **`ResourceWarning`**

  Normally, the above warnings are filtered by the default

warning filters.

It behaves as if the **`-W default`** command line option is used.

Use the **`-W error`** command line option or set the **`PYTHONWARNINGS`** environment variable to `error` to treat warnings as errors.

- Install debug hooks on memory allocators to check for:
  - Buffer underflow
  - Buffer overflow
  - Memory allocator API violation
  - Unsafe usage of the GIL

  See the **`PyMem_SetupDebugHooks()`** C function.

  It behaves as if the **`PYTHONMALLOC`** environment variable is set to `debug`.

  To enable the Python Development Mode without installing debug hooks on memory allocators, set the **`PYTHONMALLOC`** environment variable to `default`.

- Call **`faulthandler.enable()`** at Python startup to install handlers for the **`SIGSEGV`**, **`SIGFPE`**, **`SIGABRT`**, **`SIGBUS`** and **`SIGILL`** signals to dump the Python traceback on a crash.

  It behaves as if the **`-X faulthandler`** command line option is used or if the **`PYTHONFAULTHANDLER`** environment variable is set to `1`.

- Enable asyncio debug mode. For example, **`asyncio`** checks for coroutines that were not awaited and logs them.

  It behaves as if the **`PYTHONASYNCIODEBUG`** environment variable is set to `1`.

- Check the *encoding* and *errors* arguments for string encoding and decoding operations. Examples: **`open()`**,

str.encode() and **bytes.decode()**.

By default, for best performance, the *errors* argument is only checked at the first encoding/decoding error and the *encoding* argument is sometimes ignored for empty strings.

- The **io.IOBase** destructor logs `close()` exceptions.
- Set the **dev_mode** attribute of **sys.flags** to `True`.

The Python Development Mode does not enable the **tracemalloc** module by default, because the overhead cost (to performance and memory) would be too large. Enabling the **tracemalloc** module provides additional information on the origin of some errors. For example, **ResourceWarning** logs the traceback where the resource was allocated, and a buffer overflow error logs the traceback where the memory block was allocated.

The Python Development Mode does not prevent the **-O** command line option from removing **assert** statements nor from setting **__debug__** to `False`.

The Python Development Mode can only be enabled at the Python startup. Its value can be read from **sys.flags.dev_mode**.

Changed in version 3.8: The **io.IOBase** destructor now logs `close()` exceptions.

Changed in version 3.9: The *encoding* and *errors* arguments are now checked for string encoding and decoding operations.

ResourceWarning Example

Example of a script counting the number of lines of the text file specified in the command line:

```
import sys
```

```
def main():
    fp = open(sys.argv[1])
    nlines = len(fp.readlines())
    print(nlines)
    # The file is closed implicitly

if __name__ == "__main__":
    main()
```

The script does not close the file explicitly. By default, Python does not emit any warning. Example using README.txt, which has 269 lines:

```
$ python3 script.py README.txt
269
```

Enabling the Python Development Mode displays a **`ResourceWarning`** warning:

```
$ python3 -X dev script.py README.txt
269
script.py:10: ResourceWarning: unclosed file <_io.TextIO
  main()
ResourceWarning: Enable tracemalloc to get the object al
```

In addition, enabling **`tracemalloc`** shows the line where the file was opened:

```
$ python3 -X dev -X tracemalloc=5 script.py README.rst
269
script.py:10: ResourceWarning: unclosed file <_io.TextIO
  main()
Object allocated at (most recent call last):
  File "script.py", lineno 10
    main()
  File "script.py", lineno 4
    fp = open(sys.argv[1])
```

The fix is to close explicitly the file. Example using a context manager:

```
def main():
    # Close the file explicitly when exiting the with bl
    with open(sys.argv[1]) as fp:
        nlines = len(fp.readlines())
    print(nlines)
```

Not closing a resource explicitly can leave a resource open for way longer than expected; it can cause severe issues upon exiting Python. It is bad in CPython, but it is even worse in PyPy. Closing resources explicitly makes an application more deterministic and more reliable.

Bad file descriptor error example

Script displaying the first line of itself:

```
import os

def main():
    fp = open(__file__)
    firstline = fp.readline()
    print(firstline.rstrip())
    os.close(fp.fileno())
    # The file is closed implicitly

main()
```

By default, Python does not emit any warning:

```
$ python3 script.py
import os
```

The Python Development Mode shows a **`ResourceWarning`** and logs a “Bad file descriptor” error when finalizing the file object:

```
$ python3 script.py
import os
script.py:10: ResourceWarning: unclosed file <_io.TextIO
  main()
ResourceWarning: Enable tracemalloc to get the object al
Exception ignored in: <_io.TextIOWrapper name='script.py
Traceback (most recent call last):
  File "script.py", line 10, in <module>
    main()
OSError: [Errno 9] Bad file descriptor
```

`os.close(fp.fileno())` closes the file descriptor. When the file object finalizer tries to close the file descriptor again, it fails with the `Bad file descriptor` error. A file descriptor must be closed only once. In the worst case scenario, closing it twice can lead to a crash (see bpo-18748 [https://bugs.python.org/issue?@action=redirect&bpo=18748] for an example).

The fix is to remove the `os.close(fp.fileno())` line, or open the file with `closefd=False`.

`doctest` — Test interactive Python examples

Source code: Lib/doctest.py [https://github.com/python/cpython/tree/3.11/Lib/doctest.py]

The `doctest` module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module's docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of "literate testing" or "executable documentation".

Here's a complete but small example module:

```
"""
This is the "example" module.

The example module supplies one function, factorial().

>>> factorial(5)
120
"""

def factorial(n):
```

```
    """Return the factorial of n, an exact integer >= 0.

    >>> [factorial(n) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
    >>> factorial(30)
    265252859812191058636308480000000
    >>> factorial(-1)
    Traceback (most recent call last):
        ...
    ValueError: n must be >= 0

    Factorials of floats are OK, but the float must be a
    >>> factorial(30.1)
    Traceback (most recent call last):
        ...
    ValueError: n must be exact integer
    >>> factorial(30.0)
    265252859812191058636308480000000

    It must also not be ridiculously large:
    >>> factorial(1e100)
    Traceback (most recent call last):
        ...
    OverflowError: n too large
    """

    import math
    if not n >= 0:
        raise ValueError("n must be >= 0")
    if math.floor(n) != n:
        raise ValueError("n must be exact integer")
    if n+1 == n:  # catch a value like 1e300
        raise OverflowError("n too large")
    result = 1
    factor = 2
    while factor <= n:
        result *= factor
        factor += 1
```

```
    return result

if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

If you run `example.py` directly from the command line, **`doctest`** works its magic:

```
$ python example.py
$
```

There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and **`doctest`** prints a detailed log of what it's trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with:

```
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):

```

That's all you need to know to start making productive use of **doctest**! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file `Lib/test/test_doctest.py`.

Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module **M** with:

```
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

doctest then examines docstrings in module **M**.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is `***Test Failed*** N failures.`, where *N* is the number of examples that failed.

Run it with the `-v` switch instead:

```
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to **`testmod()`**, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by **`testmod()`** (so passing `-v` or not has no effect).

There is also a command line shortcut for running **`testmod()`**. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run **`testmod()`** on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on **`testmod()`**, see section Basic API.

Simple Usage: Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the **`testfile()`** function:

```
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn't need to contain a Python program! For example, perhaps `example.txt` contains this:

```
The ``example`` module
======================

Using ``factorial``
-------------------
```

```
This is an example text file in reStructuredText format.
``factorial`` from the ``example`` module:

    >>> from example import factorial

Now use it:

    >>> factorial(6)
    120
```

Running `doctest.testfile("example.txt")` then finds the error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
    120
Got:
    720
```

As with **`testmod()`**, **`testfile()`** won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as **`testmod()`**.

By default, **`testfile()`** looks for files in the calling module's directory. See section Basic API for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like **`testmod()`**, **`testfile()`**'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument *verbose*.

There is also a command line shortcut for running **`testfile()`**. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, **`doctest`** infers that it must be run with **`testfile()`**, not **`testmod()`**.

For more information on **`testfile()`**, see section Basic API.

How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if `M.__test__` exists and "is true", it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from `M.__test__` are searched, and strings are treated as if they were docstrings. In output, a key `K` in `M.__test__` appears with name

```
<name of M>.__test__.K
```

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn't trying to do an exact emulation of any specific Python shell.

```
>>> # comments are ignored
```

```
>>> x = 12
>>> x
12
>>> if x == 13:
...     print("yes")
... else:
...     print("no")
...     print("NO")
...     print("NO!!!")
...
no
NO
NO!!!
>>>
```

Any expected output must immediately follow the final `'>>> '` or `'... '` line containing the code, and the expected output (if any) extends to the next `'>>> '` or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output *are* expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the **`NORMALIZE_WHITESPACE`** option or directive is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom **`DocTestParser`** class.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```
>>> def f(x):
...     r'''Backslashes in a raw docstring: m\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n
```

  Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```
>>> def f(x):
...     '''Backslashes in a raw docstring: m\\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n
```

- The starting column doesn't matter:

```
>>> assert "Easy!"
      >>> import math
          >>> math.floor(1.9)
          1
```

  and as many leading whitespace characters are stripped from the expected output as appeared in the initial `'>>> '` line that started the example.

What's the Execution Context?

By default, each time **doctest** finds a docstring to test, it uses a *shallow copy* of **M**'s globals, so that running tests doesn't change the module's real globals, and so that one test in **M** can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in **M**, and

names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing `globs=your_dict` to **`testmod()`** or **`testfile()`** instead.

What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. 1 Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:

```
>>> [1, 2, 3].remove(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: list.remove(x): x not in list
```

That doctest succeeds if **`ValueError`** is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: multi
    line
detail
```

The last three lines (starting with **`ValueError`**) are compared against the exception's type and detail, and the rest are ignored.

Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
    ...
ValueError: multi
    line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's **`ELLIPSIS`** option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember:

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether **`ValueError`** is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.
- Each line of the traceback stack (if present) must be indented further than the first line of the example, *or* start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric

is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.

- When the **IGNORE_EXCEPTION_DETAIL** doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.
- The interactive shell omits the traceback header line for some **SyntaxError**s. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a **SyntaxError** that omits the traceback header, you will need to manually add the traceback header line to your test example.

- For some exceptions, Python displays the position of the error using ^ markers and tildes:

```
>>> 1 + None
  File "<stdin>", line 1
    1 + None
    ~~^~~~~~
TypeError: unsupported operand type(s) for +: 'int'
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the ^ marker in the wrong location:

```
>>> 1 + None
  File "<stdin>", line 1
    1 + None
    ^~~~~~~~
TypeError: unsupported operand type(s) for +: 'int'
```

Option Flags

A number of option flags control various aspects of doctest's behavior. Symbolic names for the flags are supplied as module constants, which can be bitwise ORed together and passed to various functions. The names can also be used in doctest directives, and may be passed to the doctest command line interface via the -o option.

New in version 3.4: The `-o` command line option.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example's expected output:

doctest.DONT_ACCEPT_TRUE_FOR_1

By default, if an expected output block contains just `1`, an actual output block containing just `1` or just `True` is considered to be a match, and similarly for `0` versus `False`. When **`DONT_ACCEPT_TRUE_FOR_1`** is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting "little integer" output still work in these cases. This option will probably go away, but not for several years.

doctest.DONT_ACCEPT_BLANKLINE

By default, if an expected output block contains a line containing only the string `<BLANKLINE>`, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When **`DONT_ACCEPT_BLANKLINE`** is specified, this substitution is not allowed.

doctest.NORMALIZE_WHITESPACE

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. **`NORMALIZE_WHITESPACE`** is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

doctest.ELLIPSIS

When specified, an ellipsis marker (`...`) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty

substrings, so it's best to keep usage of this simple. Complicated uses can lead to the same kinds of "oops, it matched too much!" surprises that `.*` is prone to in regular expressions.

doctest.IGNORE_EXCEPTION_DETAIL

When specified, doctests expecting exceptions pass so long as an exception of the expected type is raised, even if the details (message and fully qualified exception name) don't match.

For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail if, say, a **`TypeError`** is raised instead. It will also ignore any fully qualified name included before the exception class, which can vary between implementations and versions of Python and the code/libraries in use. Hence, all three of these variations will work with the flag specified:

```
>>> raise Exception('message')
Traceback (most recent call last):
Exception: message

>>> raise Exception('message')
Traceback (most recent call last):
builtins.Exception: message

>>> raise Exception('message')
Traceback (most recent call last):
__main__.Exception: message
```

Note that **`ELLIPSIS`** can also be used to ignore the details of the exception message, but such a test may still fail based on whether the module name is present or matches exactly.

Changed in version 3.2: **`IGNORE_EXCEPTION_DETAIL`** now also ignores any information relating to the module containing the exception under test.

doctest.SKIP

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example's output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily "commenting out" examples.

doctest.COMPARISON_FLAGS

A bitmask or'ing together all the comparison flags above.

The second group of options controls how test failures are reported:

doctest.REPORT_UDIFF

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

doctest.REPORT_CDIFF

When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

doctest.REPORT_NDIFF

When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit `1` where actual output contains letter `l`, a line is inserted with a caret marking the mismatching column positions.

doctest.REPORT_ONLY_FIRST_FAILURE

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide

incorrect examples that fail independently of the first failure. When **REPORT_ONLY_FIRST_FAILURE** is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

doctest.FAIL_FAST

When specified, exit after the first failing example and don't attempt to run the remaining examples. Thus, the number of failures reported will be at most 1. This flag may be useful during debugging, since examples after the first failure won't even produce debugging output.

The doctest command line accepts the option `-f` as a shorthand for `-o FAIL_FAST`.

New in version 3.4.

doctest.REPORTING_FLAGS

A bitmask or'ing together all the reporting flags above.

There is also a way to register new option flag names, though this isn't useful unless you intend to extend **doctest** internals via subclassing:

doctest.register_optionflag(*name*)

Create a new option flag with a given name, and return the new flag's integer value. **register_optionflag()** can be used when subclassing **OutputChecker** or **DocTestRunner** to create new options that are supported by your subclasses. **register_optionflag()** should always be called using the following idiom:

```
MY_FLAG = register_optionflag('MY_FLAG')
```

Directives

Doctest directives may be used to modify the option flags for an individual example. Doctest directives are special Python comments

following an example's source code:

```
directive             ::=  "#" "doctest:" directive_opti
directive_options     ::=  directive_option ("," directi
directive_option      ::=  on_or_off directive_option_na
on_or_off             ::=  "+" | "-"
directive_option_name ::=  "DONT_ACCEPT_BLANKLINE" | "NO
```

Whitespace is not allowed between the `+` or `-` and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use `+` to enable the named behavior, or `-` to disable it.

For example, this test passes:

```
>>> print(list(range(20)))  # doctest: +NORMALIZE_WHITES
[0,   1,  2,  3,  4,  5,  6,  7,  8,  9,
10,  11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS, +NORMA
[0,    1, ...,   18,    19]
```

If multiple directive comments are used for a single example, then they are combined:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS
...                         # doctest: +NORMALIZE_WHITES
```

```
[0,    1, ...,   18,    19]
```

As the previous example shows, you can add `...` lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```
>>> print(list(range(5)) + list(range(10, 20)) + list(ra
... # doctest: +ELLIPSIS
[0, ..., 4, 10, ..., 19, 30, ..., 39]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via `+` in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via `-` in a directive can be useful.

Warnings

`doctest` is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn't guarantee about output. For example, when printing a set, Python doesn't guarantee that the element is printed in any particular order, so a test like

```
>>> foo()
{"Hermione", "Harry"}
```

is vulnerable! One workaround is to do

```
>>> foo() == {"Hermione", "Harry"}
True
```

instead. Another is to do

```
>>> d = sorted(foo())
>>> d
['Harry', 'Hermione']
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```
>>> id(1.0)  # certain to fail some of the time
7948648
>>> class C: pass
>>> C()  # the default repr() for instances embeds an ac
<C object at 0x00AC18F0>
```

The **ELLIPSIS** directive gives a nice approach for the last example:

```
>>> C()  # doctest: +ELLIPSIS
<C object at 0x...>
```

Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```
>>> 1./7  # risky
0.14285714285714285
>>> print(1./7) # safer
0.142857142857
>>> print(round(1./7, 6)) # much safer
0.142857
```

Numbers of the form `I/2.**J` are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```
>>> 3./4  # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.

Basic API

The functions **testmod()** and **testfile()** provide a simple

interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections Simple Usage: Checking Examples in Docstrings and Simple Usage: Checking Examples in a Text File.

doctest.testfile(*filename*, *module_relative=True*, *name=None*, *package=None*, *globs=None*, *verbose=None*, *report=True*, *optionflags=0*, *extraglobs=None*, *raise_on_error=False*, *parser=DocTestParser()*, *encoding=None*)

All arguments except *filename* are optional, and should be specified in keyword form.

Test examples in the file named *filename*. Return `(failure_count, test_count)`.

Optional argument *module_relative* specifies how the filename should be interpreted:

- If *module_relative* is `True` (the default), then *filename* specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the *package* argument is specified, then it is relative to that package. To ensure OS-independence, *filename* should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If *module_relative* is `False`, then *filename* specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument *name* gives the name of the test; by default, or if `None`, `os.path.basename(filename)` is used.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to

specify *package* if *module_relative* is `False`.

Optional argument *globs* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if `None`, a new empty dict is used.

Optional argument *extraglobs* gives a dict merged into the globals used to execute examples. This works like **`dict.update()`**: if *globs* and *extraglobs* have a common key, the associated value in *extraglobs* appears in the combined dict. By default, or if `None`, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an *extraglobs* dict mapping the generic name to the subclass to be tested.

Optional argument *verbose* prints lots of stuff if true, and prints only failures if false; by default, or if `None`, it's true if and only if `'-v'` is in `sys.argv`.

Optional argument *report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).

Optional argument *optionflags* (default value 0) takes the bitwise OR of option flags. See section Option Flags.

Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a **`DocTestParser`** (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should

be used to convert the file to unicode.

doctest.testmod(*m=None*, *name=None*, *globs=None*, *verbose=None*, *report=True*, *optionflags=0*, *extraglobs=None*, *raise_on_error=False*, *exclude_empty=False*)

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module **`__main__`** if *m* is not supplied or is `None`), starting with `m.__doc__`.

Also test examples reachable from dict `m.__test__`, if it exists and is not `None`. `m.__test__` maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return `(failure_count, test_count)`.

Optional argument *name* gives the name of the module; by default, or if `None`, `m.__name__` is used.

Optional argument *exclude_empty* defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using **`doctest.master.summarize()`** in conjunction with **`testmod()`** continues to get output for objects with no tests. The *exclude_empty* argument to the newer **`DocTestFinder`** constructor defaults to true.

Optional arguments *extraglobs*, *verbose*, *report*, *optionflags*, *raise_on_error*, and *globs* are the same as for function **`testfile()`** above, except that *globs* defaults to `m.__dict__`.

doctest.run_docstring_examples(*f*, *globs*, *verbose=False*,

name = *'NoName'*, *compileflags* = *None*, *optionflags* = *0*)

Test examples associated with object *f*; for example, *f* may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to `"NoName"`.

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By default, or if `None`, flags are deduced corresponding to the set of future features found in *globs*.

Optional argument *optionflags* works as for function **`testfile()`** above.

Unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. **`doctest`** provides two functions that can be used to create **`unittest`** test suites from modules and text files containing doctests. To integrate with **`unittest`** test discovery, include a **`load_tests()`** function in your test module:

```
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_d
    return tests
```

There are two main functions for creating **`unittest.TestSuite`**

instances from text files and modules with doctests:

doctest.DocFileSuite(**paths*, *module_relative=True*, *package=None*, *setUp=None*, *tearDown=None*, *globs=None*, *optionflags=0*, *parser=DocTestParser()*, *encoding=None*)

Convert doctest tests from one or more text files to a **unittest.TestSuite**.

The returned **unittest.TestSuite** is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a **failureException** exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.

Options may be provided as keyword arguments:

Optional argument *module_relative* specifies how the filenames in *paths* should be interpreted:

- If *module_relative* is `True` (the default), then each filename in *paths* specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the *package* argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If *module_relative* is `False`, then each filename in *paths* specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in *paths*. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is

an error to specify *package* if *module_relative* is `False`.

Optional argument *setUp* specifies a set-up function for the test suite. This is called before running the tests in each file. The *setUp* function will be passed a **`DocTest`** object. The setUp function can access the test globals as the *globs* attribute of the test passed.

Optional argument *tearDown* specifies a tear-down function for the test suite. This is called after running the tests in each file. The *tearDown* function will be passed a **`DocTest`** object. The setUp function can access the test globals as the *globs* attribute of the test passed.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *optionflags* specifies the default doctest options for the tests, created by or-ing together individual option flags. See section Option Flags. See function **`set_unittest_reportflags()`** below for a better way to set reporting options.

Optional argument *parser* specifies a **`DocTestParser`** (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

The global `__file__` is added to the globals provided to doctests loaded from a text file using **`DocFileSuite()`**.

doctest.DocTestSuite(*module=None, globs=None, extraglobs=None, test_finder=None, setUp=None, tearDown=None, checker=None*)

Convert doctest tests for a module to a **`unittest.TestSuite`**.

The returned **`unittest.TestSuite`** is to be run by the

unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a **failureException** exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument *module* provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not specified, the module calling this function is used.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globs*. By default, no extra globals are used.

Optional argument *test_finder* is the **DocTestFinder** object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function **DocFileSuite()** above.

This function uses the same search technique as **testmod()**.

Changed in version 3.5: **DocTestSuite()** returns an empty **unittest.TestSuite** if *module* contains no docstrings instead of raising **ValueError**.

Under the covers, **DocTestSuite()** creates a **unittest.TestSuite** out of **doctest.DocTestCase** instances, and **DocTestCase** is a subclass of **unittest.TestCase**. **DocTestCase** isn't documented here (it's an internal detail), but studying its code can answer questions about the exact details of **unittest** integration.

Similarly, **DocFileSuite()** creates a **unittest.TestSuite** out of **doctest.DocFileCase** instances, and **DocFileCase** is a

subclass of **DocTestCase**.

So both ways of creating a **unittest.TestSuite** run instances of **DocTestCase**. This is important for a subtle reason: when you run **doctest** functions yourself, you can control the **doctest** options in use directly, by passing option flags to **doctest** functions. However, if you're writing a **unittest** framework, **unittest** ultimately controls when and how tests get run. The framework author typically wants to control **doctest** reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through **unittest** to **doctest** test runners.

For this reason, **doctest** also supports a notion of **doctest** reporting flags specific to **unittest** support, via this function:

doctest.set_unittest_reportflags(*flags*)

Set the **doctest** reporting flags to use.

Argument *flags* takes the bitwise OR of option flags. See section Option Flags. Only "reporting flags" can be used.

This is a module-global setting, and affects all future doctests run by module **unittest**: the **runTest()** method of **DocTestCase** looks at the option flags specified for the test case when the **DocTestCase** instance was constructed. If no reporting flags were specified (which is the typical and expected case), **doctest**'s **unittest** reporting flags are bitwise ORed into the option flags, and the option flags so augmented are passed to the **DocTestRunner** instance created to run the doctest. If any reporting flags were specified when the **DocTestCase** instance was constructed, **doctest**'s **unittest** reporting flags are ignored.

The value of the **unittest** reporting flags in effect before the function was called is returned by the function.

Advanced API

The basic API is a simple wrapper that's intended to make doctest

easy to use. It is fairly flexible, and should meet most users' needs; however, if you require more fine-grained control over testing, or wish to extend doctest's capabilities, then you should use the advanced API.

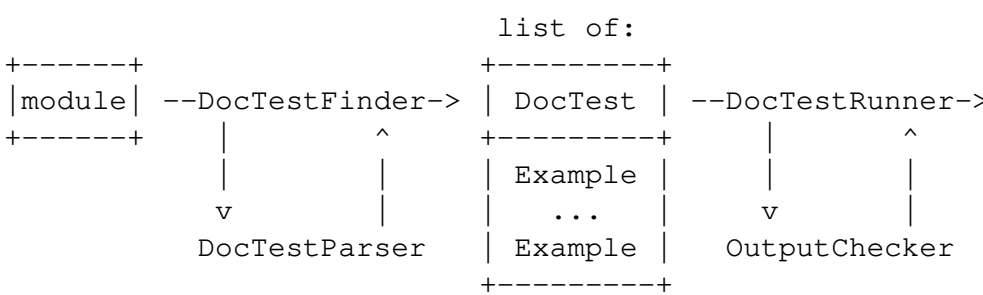
The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **`Example`**: A single Python statement, paired with its expected output.
- **`DocTest`**: A collection of **`Example`**s, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **`DocTestFinder`**: Finds all docstrings in a given module, and uses a **`DocTestParser`** to create a **`DocTest`** from every docstring that contains interactive examples.
- **`DocTestParser`**: Creates a **`DocTest`** object from a string (such as an object's docstring).
- **`DocTestRunner`**: Executes the examples in a **`DocTest`**, and uses an **`OutputChecker`** to verify their output.
- **`OutputChecker`**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:



DocTest Objects

class doctest.DocTest(*examples*, *globs*, *name*, *filename*, *lineno*, *docstring*)

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

DocTest defines the following attributes. They are initialized by the constructor, and should not be modified directly.

examples

A list of **Example** objects encoding the individual interactive Python examples that should be run by this test.

globs

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in **globs** after the test is run.

name

A string name identifying the **DocTest**. Typically, this is the name of the object or file that the test was extracted from.

filename

The name of the file that this **DocTest** was extracted from; or `None` if the filename is unknown, or if the **DocTest** was not extracted from a file.

lineno

The line number within **filename** where this **DocTest** begins, or `None` if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

docstring

The string that the test was extracted from, or `None` if the string is unavailable, or if the test was not extracted from a string.

Example Objects

class doctest.Example(*source*, *want*, *exc_msg*=*None*, *lineno*=*0*, *indent*=*0*, *options*=*None*)

A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

`Example` defines the following attributes. They are initialized by the constructor, and should not be modified directly.

source

A string containing the example's source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.

want

The expected output from running the example's source code (either from stdout, or a traceback in case of exception). **`want`** ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

exc_msg

The exception message generated by the example, if the example is expected to generate an exception; or `None` if it is not expected to generate an exception. This exception message is compared against the return value of **`traceback.format_exception_only()`**. **`exc_msg`** ends with a newline unless it's `None`. The constructor adds a newline if needed.

lineno

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

indent

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

options

A dictionary mapping from option flags to `True` or `False`, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the **DocTestRunner**'s **optionflags**). By default, no options are set.

DocTestFinder objects

class doctest.DocTestFinder(*verbose*=*False*, *parser*=*DocTestParser()*, *recurse*=*True*, *exclude_empty*=*True*)

A processing class used to extract the **DocTest**s that are relevant to a given object, from its docstring and the docstrings of its contained objects. **DocTest**s can be extracted from modules, classes, functions, methods, staticmethods, classmethods, and properties.

The optional argument *verbose* can be used to display the objects searched by the finder. It defaults to `False` (no output).

The optional argument *parser* specifies the **DocTestParser** object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument *recurse* is false, then **DocTestFinder.find()** will only examine the given object, and not any contained objects.

If the optional argument *exclude_empty* is false, then **`DocTestFinder.find()`** will include tests for objects with empty docstrings.

`DocTestFinder` defines the following method:

find(*obj[, name][, module][, globs][, extraglobs]*)

Return a list of the **`DocTest`**s that are defined by *obj*'s docstring, or by any of its contained objects' docstrings.

The optional argument *name* specifies the object's name; this name will be used to construct names for the returned **`DocTest`**s. If *name* is not specified, then `obj.__name__` is used.

The optional parameter *module* is the module that contains the given object. If the module is not specified or is `None`, then the test finder will attempt to automatically determine the correct module. The object's module is used:

- As a default namespace, if *globs* is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than *module* are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If *module* is `False`, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if *module* is `False`, or is `None` but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each **`DocTest`** is formed by combining *globs* and *extraglobs* (bindings in *extraglobs* override bindings in *globs*). A new shallow copy of the globals

dictionary is created for each **DocTest**. If *globs* is not specified, then it defaults to the module's *__dict__*, if specified, or `{}` otherwise. If *extraglobs* is not specified, then it defaults to `{}`.

DocTestParser objects

class doctest.DocTestParser

A processing class used to extract interactive examples from a string, and use them to create a **DocTest** object.

DocTestParser defines the following methods:

get_doctest(*string*, *globs*, *name*, *filename*, *lineno*)

Extract all doctest examples from the given string, and collect them into a **DocTest** object.

globs, *name*, *filename*, and *lineno* are attributes for the new **DocTest** object. See the documentation for **DocTest** for more information.

get_examples(*string*, *name*='<*string*>')

Extract all doctest examples from the given string, and return them as a list of **Example** objects. Line numbers are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

parse(*string*, *name*='<*string*>')

Divide the given string into examples and intervening text, and return them as a list of alternating **Example**s and strings. Line numbers for the **Example**s are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

DocTestRunner objects

class doctest.DocTestRunner(*checker=None, verbose=None, optionflags=0*)

A processing class used to execute and verify the interactive examples in a **DocTest**.

The comparison between expected outputs and actual outputs is done by an **OutputChecker**. This comparison may be customized with a number of option flags; see section Option Flags for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of **OutputChecker** to the constructor.

The test runner's display output can be controlled in two ways. First, an output function can be passed to **TestRunner.run()**; this function will be called with strings that should be displayed. It defaults to `sys.stdout.write`. If capturing the output is not sufficient, then the display output can be also customized by subclassing DocTestRunner, and overriding the methods **report_start()**, **report_success()**, **report_unexpected_exception()**, and **report_failure()**.

The optional keyword argument *checker* specifies the **OutputChecker** object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument *verbose* controls the **DocTestRunner**'s verbosity. If *verbose* is `True`, then information is printed about each example, as it is run. If *verbose* is `False`, then only failures are printed. If *verbose* is unspecified, or `None`, then verbose output is used iff the command-line switch `-v` is used.

The optional keyword argument *optionflags* can be used to control how the test runner compares expected output to actual output, and how it displays failures. For more information, see section Option Flags.

DocTestParser defines the following methods:

report_start(*out*, *test*, *example*)

Report that the test runner is about to process the given example. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

example is the example about to be processed. *test* is the test *containing example*. *out* is the output function that was passed to **DocTestRunner.run()**.

report_success(*out*, *test*, *example*, *got*)

Report that the given example ran successfully. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

example is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

report_failure(*out*, *test*, *example*, *got*)

Report that the given example failed. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

example is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

report_unexpected_exception(*out*, *test*, *example*, *exc_info*)

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

example is the example about to be processed. *exc_info* is a tuple containing information about the unexpected exception (as returned by **sys.exc_info()**). *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner.run()**.

run(*test*, *compileflags*=*None*, *out*=*None*, *clear_globs*=*True*)

Run the examples in *test* (a **DocTest** object), and display the results using the writer function *out*.

The examples are run in the namespace `test.globs`. If *clear_globs* is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use *clear_globs*=*False*.

compileflags gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to *globs*.

The output of each example is checked using the **DocTestRunner**'s output checker, and the results are formatted by the **DocTestRunner.report_*()** methods.

summarize(*verbose*=*None*)

Print a summary of all the test cases that have been run by this DocTestRunner, and return a named tuple `TestResults(failed, attempted)`.

The optional *verbose* argument controls how detailed the summary is. If the verbosity is not specified, then the **DocTestRunner**'s verbosity is used.

OutputChecker objects

class doctest.OutputChecker

A class used to check the whether the actual output from a

doctest example matches the expected output. **OutputChecker** defines two methods: **check_output()**, which compares a given pair of outputs, and returns `True` if they match; and **output_difference()**, which returns a string describing the differences between two outputs.

OutputChecker defines the following methods:

check_output(*want*, *got*, *optionflags*)

Return `True` iff the actual output from an example (*got*) matches the expected output (*want*). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section Option Flags for more information about option flags.

output_difference(*example*, *got*, *optionflags*)

Return a string describing the differences between the expected output for a given example (*example*) and the actual output (*got*). *optionflags* is the set of option flags used to compare *want* and *got*.

Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, **pdb**.
- The **DebugRunner** class is a subclass of **DocTestRunner** that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.
- The **unittest** cases generated by **DocTestSuite()**

support the **`debug()`** method defined by **`unittest.TestCase`**.

- You can add a call to **`pdb.set_trace()`** in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```
"""
>>> def f(x):
...     g(x*2)
>>> def g(x):
...     print(x+3)
...     import pdb; pdb.set_trace()
>>> f(3)
9
"""
```

Then an interactive Python session may look like this:

```
>>> import a, doctest
>>> doctest.testmod(a)
--Return--
> <doctest a[1]>(3)g()->None
-> import pdb; pdb.set_trace()
(Pdb) list
  1     def g(x):
  2         print(x+3)
  3  ->     import pdb; pdb.set_trace()
[EOF]
(Pdb) p x
6
(Pdb) step
--Return--
> <doctest a[0]>(2)f()->None
-> g(x*2)
(Pdb) list
  1     def f(x):
```

```
  2  ->     g(x*2)
[EOF]
(Pdb) p x
3
(Pdb) step
--Return--
> <doctest a[2]>(1)?()->None
-> f(3)
(Pdb) cont
(0, 3)
>>>
```

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

doctest.script_from_examples(*s*)

Convert text with examples to a script.

Argument *s* is a string containing doctest examples. The string is converted to a Python script, where doctest examples in *s* are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```
import doctest
print(doctest.script_from_examples(r"""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print(x+y)
    3
"""))
```

displays:

```
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
```

```
print(x+y)
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

doctest.testsource(*module*, *name*)

Convert the doctest for an object to a script.

Argument *module* is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument *name* is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for **`script_from_examples()`** above. For example, if module `a.py` contains a top-level function **`f()`**, then

```
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function **`f()`**'s docstring, with doctests converted to code, and the rest placed in comments.

doctest.debug(*module*, *name*, *pm*=*False*)

Debug the doctests for an object.

The *module* and *name* arguments are the same as for function **`testsource()`** above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, **`pdb`**.

A shallow copy of `module.__dict__` is used for both local and global execution context.

Optional argument *pm* controls whether post-mortem debugging is used. If *pm* has a true value, the script file is run

directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via **pdb.post_mortem()**, passing the traceback object from the unhandled exception. If *pm* is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate **exec()** call to **pdb.run()**.

doctest.debug_src(*src*, *pm*=*False*, *globs*=*None*)

Debug the doctests in a string.

This is like function **debug()** above, except that a string containing doctest examples is specified directly, via the *src* argument.

Optional argument *pm* has the same meaning as in function **debug()** above.

Optional argument *globs* gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The **DebugRunner** class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially **DebugRunner**'s docstring (which is a doctest!) for more details:

class doctest.DebugRunner(*checker*=*None*, *verbose*=*None*, *optionflags*=*0*)

A subclass of **DocTestRunner** that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an **UnexpectedException** exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a **DocTestFailure** exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and

methods, see the documentation for **DocTestRunner** in section Advanced API.

There are two exceptions that may be raised by **DebugRunner** instances:

exception doctest.DocTestFailure(*test*, *example*, *got*)

An exception raised by **DocTestRunner** to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

DocTestFailure defines the following attributes:

DocTestFailure.test

The **DocTest** object that was being run when the example failed.

DocTestFailure.example

The **Example** that failed.

DocTestFailure.got

The example's actual output.

exception doctest.UnexpectedException(*test*, *example*, *exc_info*)

An exception raised by **DocTestRunner** to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

UnexpectedException defines the following attributes:

UnexpectedException.test

The **DocTest** object that was being run when the example failed.

UnexpectedException.example

The **Example** that failed.

UnexpectedException.exc_info

A tuple containing information about the unexpected exception, as returned by `sys.exc_info()`.

Soapbox

As mentioned in the introduction, `doctest` has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my `doctest` examples stops working after a "harmless" change.

Doctest also makes an excellent tool for regression testing, especially if you don't skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples.

This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It's a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using **`testfile()`** or **`DocFileSuite()`**. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

```
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.FAIL_FAST
    if len(sys.argv) > 1:
        name = sys.argv[1]
        if name in globals():
            obj = globals()[name]
        else:
            obj = __test__[name]
        doctest.run_docstring_examples(obj, globals(), r
                                       optionflags=flags
    else:
        fail, total = doctest.testmod(optionflags=flags)
        print("{} failures out of {} tests".format(fail,
```

Footnotes

1

Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.

`unittest` — Unit testing framework

Source code: Lib/unittest/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/unittest/__init__.py]

(If you are already familiar with the basic concepts of testing, you might want to skip to the list of assert methods.)

The `unittest` unit testing framework was originally inspired by JUnit and has a similar flavor as major unit testing frameworks in other languages. It supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework.

To achieve this, `unittest` supports some important concepts in an object-oriented way:

test fixture
: A *test fixture* represents the preparation needed to perform one or more tests, and any associated cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

test case
: A *test case* is the individual unit of testing. It checks for a specific response to a particular set of inputs. `unittest` provides a base class, `TestCase`, which may be used to create new test cases.

test suite
: A *test suite* is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

test runner

A *test runner* is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as Buildbot [https://buildbot.net/], Jenkins [https://jenkins.io/], GitHub Actions [https://github.com/features/actions], or AppVeyor [https://www.appveyor.com/].

Basic example

The **unittest** module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three string methods:

```
import unittest

class TestStringMethods(unittest.TestCase):

    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing **unittest.TestCase**. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.

The crux of each test is a call to **assertEqual()** to check for an expected result; **assertTrue()** or **assertFalse()** to verify a condition; or **assertRaises()** to verify that a specific exception gets raised. These methods are used instead of the **assert** statement so the test runner can accumulate all test results and

produce a report.

The **`setUp()`** and **`tearDown()`** methods allow you to define instructions that will be executed before and after each test method. They are covered in more detail in the section Organizing test code.

The final block shows a simple way to run the tests. **`unittest.main()`** provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```
...
----------------------------------------------------------------------
Ran 3 tests in 0.000s

OK
```

Passing the `-v` option to your test script will instruct **`unittest.main()`** to enable a higher level of verbosity, and produce the following output:

```
test_isupper (__main__.TestStringMethods.test_isupper) .
test_split (__main__.TestStringMethods.test_split) ... o
test_upper (__main__.TestStringMethods.test_upper) ... o

----------------------------------------------------------------------
Ran 3 tests in 0.001s

OK
```

The above examples show the most commonly used **`unittest`** features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.

Changed in version 3.11: The behavior of returning a value from a test method (other than the default `None` value), is now deprecated.

Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

Test modules can be specified by file path as well:

```
python -m unittest tests/test_something.py
```

This allows you to use the shell filename completion to specify the test module. The file specified must still be importable as a module. The path is converted to a module name by removing the '.py' and converting path separators into '.'. If you want to execute a test file that isn't importable as a module you should execute the file directly instead.

You can run tests with more detail (higher verbosity) by passing in the -v flag:

```
python -m unittest -v test_module
```

When executed without arguments Test Discovery is started:

```
python -m unittest
```

For a list of all the command-line options:

```
python -m unittest -h
```

Changed in version 3.2: In earlier versions it was only possible to run individual test methods and not modules or classes.

Command-line options

unittest supports these command-line options:

-b, --buffer

The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

-c, --catch

`Control-C` during the test run waits for the current test to end and then reports all the results so far. A second `Control-C` raises the normal **`KeyboardInterrupt`** exception.

See Signal Handling for the functions that provide this functionality.

-f, --failfast

Stop the test run on the first error or failure.

-k

Only run test methods and classes that match the pattern or substring. This option may be used multiple times, in which case all test cases that match any of the given patterns are included.

Patterns that contain a wildcard character (`*`) are matched against the test name using **`fnmatch.fnmatchcase()`**; otherwise simple case-sensitive substring matching is used.

Patterns are matched against the fully qualified test method name as imported by the test loader.

For example, `-k foo` matches `foo_tests.SomeTest.test_something`, `bar_tests.SomeTest.test_foo`, but not `bar_tests.FooTest.test_something`.

--locals

Show local variables in tracebacks.

New in version 3.2: The command-line options `-b`, `-c` and `-f` were

added.

New in version 3.5: The command-line option `--locals`.

New in version 3.7: The command-line option `-k`.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.

Test Discovery

New in version 3.2.

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in **`TestLoader.discover()`**, but can also be used from the command line. The basic command-line usage is:

```
cd project_directory
python -m unittest discover
```

Note

As a shortcut, `python -m unittest` is the equivalent of `python -m unittest discover`. If you want to pass arguments to test discovery the `discover` sub-command must be used explicitly.

The `discover` sub-command has the following options:

-v, --verbose
: Verbose output

-s, --start-directory directory
: Directory to start discovery (`.` default)

-p, --pattern pattern

Pattern to match test files (`test*.py` default)

-t, --top-level-directory directory

Top level directory of project (defaults to start directory)

The **`-s`**, **`-p`**, and **`-t`** options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p "*_t
python -m unittest discover project_directory "*_test.py
```

As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

Caution

Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the load_tests protocol.

Changed in version 3.4: Test discovery supports namespace packages

for the start directory. Note that you need to specify the top level directory too (e.g. `python -m unittest discover -s root/namespace -t root`).

Changed in version 3.11: Python 3.11 dropped the namespace packages support. It has been broken since Python 3.7. Start directory and subdirectories containing tests must be regular package that have `__init__.py` file.

Directories containing start directory still can be a namespace package. In this case, you need to specify start directory as dotted package name, and target directory explicitly. For example:

```
# proj/  <-- current directory
#   namespace/
#     mypkg/
#       __init__.py
#       test_mypkg.py

python -m unittest discover -s namespace.mypkg -t .
```

Organizing test code

The basic building blocks of unit testing are *test cases* — single scenarios that must be set up and checked for correctness. In **`unittest`**, test cases are represented by **`unittest.TestCase`** instances. To make your own test cases you must write subclasses of **`TestCase`** or use **`FunctionTestCase`**.

The testing code of a **`TestCase`** instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest **`TestCase`** subclass will simply implement a test method (i.e. a method whose name starts with `test`) in order to perform specific testing code:

```
import unittest

class DefaultWidgetSizeTestCase(unittest.TestCase):
```

```
    def test_default_widget_size(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the **`assert*()`** methods provided by the **`TestCase`** base class. If the test fails, an exception will be raised with an explanatory message, and **`unittest`** will identify the test case as a *failure*. Any other exceptions will be treated as *errors*.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called **`setUp()`**, which the testing framework will automatically call for every single test we run:

```
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def test_default_widget_size(self):
        self.assertEqual(self.widget.size(), (50,50),
                         'incorrect default size')

    def test_widget_resize(self):
        self.widget.resize(100,150)
        self.assertEqual(self.widget.size(), (100,150),
                         'wrong size after resize')
```

Note

The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the **`setUp()`** method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a **tearDown()** method that tidies up after the test method has been run:

```
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
```

If **setUp()** succeeded, **tearDown()** will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a *test fixture*. A new TestCase instance is created as a unique test fixture used to execute each individual test method. Thus **setUp()**, **tearDown()**, and **__init__()** will be called once per test.

It is recommended that you use TestCase implementations to group tests together according to the features they test. **unittest** provides a mechanism for this: the *test suite*, represented by **unittest**'s **TestSuite** class. In most cases, calling **unittest.main()** will do the right thing and collect all the module's test cases for you and execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_widget_si
    suite.addTest(WidgetTestCase('test_widget_resize'))
    return suite

if __name__ == '__main__':
    runner = unittest.TextTestRunner()
    runner.run(suite())
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.

Re-using old test code

Some users will find that they have existing test code that they would like to run from **`unittest`**, without converting every old test function to a **`TestCase`** subclass.

For this reason, **`unittest`** provides a **`FunctionTestCase`** class. This subclass of **`TestCase`** can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```
testcase = unittest.FunctionTestCase(testSomething,
```

```
                                    setUp=makeSomethin
                                    tearDown=deleteSome
```

Note

Even though **FunctionTestCase** can be used to quickly convert an existing test base over to a **unittest**-based system, this approach is not recommended. Taking the time to set up proper **TestCase** subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the **doctest** module. If so, **doctest** provides a **DocTestSuite** class that can automatically build **unittest.TestSuite** instances from the existing **doctest**-based tests.

Skipping tests and expected failures

New in version 3.1.

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an "expected failure," a test that is broken and will fail, but shouldn't be counted as a failure on a **TestResult**.

Skipping a test is simply a matter of using the **skip()** decorator or one of its conditional variants, calling **TestCase.skipTest()** within a **setUp()** or test method, or raising **SkipTest** directly.

Basic skipping looks like this:

```
class MyTestCase(unittest.TestCase):

    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3),
                     "not supported in this library vers
```

```
    def test_format(self):
        # Tests that work for only a certain version of
        pass

    @unittest.skipUnless(sys.platform.startswith("win"),
    def test_windows_support(self):
        # windows specific testing code
        pass

    def test_maybe_skipped(self):
        if not external_resource_available():
            self.skipTest("external resource not availab
        # test code that depends on the external resourc
        pass
```

This is the output of running the example above in verbose mode:

```
test_format (__main__.MyTestCase.test_format) ... skippe
test_nothing (__main__.MyTestCase.test_nothing) ... skip
test_maybe_skipped (__main__.MyTestCase.test_maybe_skipp
test_windows_support (__main__.MyTestCase.test_windows_s

----------------------------------------------------------
Ran 4 tests in 0.005s

OK (skipped=4)
```

Classes can be skipped just like methods:

```
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the **`expectedFailure()`** decorator.

```
class ExpectedFailureTestCase(unittest.TestCase):
```

```
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls **`skip()`** on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
    return unittest.skip("{!r} doesn't have {!r}".format
```

The following decorators and exception implement test skipping and expected failures:

@unittest.skip(*reason*)

Unconditionally skip the decorated test. *reason* should describe why the test is being skipped.

@unittest.skipIf(*condition*, *reason*)

Skip the decorated test if *condition* is true.

@unittest.skipUnless(*condition*, *reason*)

Skip the decorated test unless *condition* is true.

@unittest.expectedFailure

Mark the test as an expected failure or error. If the test fails or errors in the test function itself (rather than in one of the *test fixture* methods) then it will be considered a success. If the test passes, it will be considered a failure.

exception unittest.SkipTest(*reason*)

This exception is raised to skip a test.

Usually you can use **`TestCase.skipTest()`** or one of the skipping decorators instead of raising this directly.

Skipped tests will not have **`setUp()`** or **`tearDown()`** run around them. Skipped classes will not have **`setUpClass()`** or **`tearDownClass()`** run. Skipped modules will not have **`setUpModule()`** or **`tearDownModule()`** run.

Distinguishing test iterations using subtests

New in version 3.4.

When there are very small differences among your tests, for instance some parameters, unittest allows you to distinguish them inside the body of a test method using the **`subTest()`** context manager.

For example, the following test:

```
class NumbersTest(unittest.TestCase):

    def test_even(self):
        """
        Test that numbers between 0 and 5 are all even.
        """
        for i in range(0, 6):
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

will produce the following output:

```
======================================================================
FAIL: test_even (__main__.NumbersTest.test_even) (i=1)
Test that numbers between 0 and 5 are all even.
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0
```

```
======================================================================
FAIL: test_even (__main__.NumbersTest.test_even) (i=3)
Test that numbers between 0 and 5 are all even.
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0

======================================================================
FAIL: test_even (__main__.NumbersTest.test_even) (i=5)
Test that numbers between 0 and 5 are all even.
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0
```

Without using a subtest, execution would stop after the first failure, and the error would be less easy to diagnose because the value of `i` wouldn't be displayed:

```
======================================================================
FAIL: test_even (__main__.NumbersTest.test_even)
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```

Classes and functions

This section describes in depth the API of **`unittest`**.

Test cases

class unittest.TestCase(*methodName='runTest'*)

Instances of the **TestCase** class represent the logical test units in the **unittest** universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of **TestCase** will run a single base method: the method named *methodName*. In most uses of **TestCase**, you will neither change the *methodName* nor reimplement the default `runTest()` method.

Changed in version 3.2: **TestCase** can be instantiated successfully without providing a *methodName*. This makes it easier to experiment with **TestCase** from the interactive interpreter.

TestCase instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

setUp()

Method called to prepare the test fixture. This is called immediately before calling the test method; other than **AssertionError** or **SkipTest**, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

tearDown()

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be

particularly careful about checking internal state. Any exception, other than **AssertionError** or **SkipTest**, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the **setUp()** succeeds, regardless of the outcome of the test method. The default implementation does nothing.

setUpClass()

A class method called before tests in an individual class are run. `setUpClass` is called with the class as the only argument and must be decorated as a **classmethod()**:

```
@classmethod
def setUpClass(cls):
    ...
```

See Class and Module Fixtures for more details.

New in version 3.2.

tearDownClass()

A class method called after tests in an individual class have run. `tearDownClass` is called with the class as the only argument and must be decorated as a **classmethod()**:

```
@classmethod
def tearDownClass(cls):
    ...
```

See Class and Module Fixtures for more details.

New in version 3.2.

run(*result=None*)

Run the test, collecting the result into the

TestResult object passed as *result*. If *result* is omitted or `None`, a temporary result object is created (by calling the **defaultTestResult()** method) and used. The result object is returned to **run()**'s caller.

The same effect may be had by simply calling the **TestCase** instance.

Changed in version 3.3: Previous versions of `run` did not return the result. Neither did calling an instance.

skipTest(*reason*)

Calling this during a test method or **setUp()** skips the current test. See Skipping tests and expected failures for more information.

New in version 3.1.

subTest(*msg=None*, ***params*)

Return a context manager which executes the enclosed code block as a subtest. *msg* and *params* are optional, arbitrary values which are displayed whenever a subtest fails, allowing you to identify them clearly.

A test case can contain any number of subtest declarations, and they can be arbitrarily nested.

See Distinguishing test iterations using subtests for more information.

New in version 3.4.

debug()

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The **TestCase** class provides several assert methods to

check for and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods):

Method	Checks that
`assertEqual(a, b)`	`a == b`
`assertNotEqual(a, b)`	`a != b`
`assertTrue(x)`	`bool(x) is True`
`assertFalse(x)`	`bool(x) is False`
`assertIs(a, b)`	`a is b`
`assertIsNot(a, b)`	`a is not b`
`assertIsNone(x)`	`x is None`
`assertIsNotNone(x)`	`x is not None`
`assertIn(a, b)`	`a in b`
`assertNotIn(a, b)`	`a not in b`
`assertIsInstance(a, b)`	`isinstance(a, b)`
`assertNotIsInstance(a, b)`	`not isinstance(a, b)`

All the assert methods accept a *msg* argument that, if specified, is used as the error message on failure (see also `longMessage`). Note that the *msg* keyword argument can be passed to `assertRaises()`, `assertRaisesRegex()`, `assertWarns()`, `assertWarnsRegex()` only when they are used as a context manager.

assertEqual(*first*, *second*, *msg*=*None*)

Test that *first* and *second* are equal. If the values do not compare equal, the test will fail.

In addition, if *first* and *second* are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with `addTypeEqualityFunc()` the type-specific equality function will be called in order to generate a more useful default error message (see also the list of type-specific methods).

Changed in version 3.1: Added the automatic calling of type-specific equality function.

Changed in version 3.2: `assertMultiLineEqual()`

added as the default type equality function for comparing strings.

assertNotEqual(*first*, *second*, *msg*=*None*)

Test that *first* and *second* are not equal. If the values do compare equal, the test will fail.

assertTrue(*expr*, *msg*=*None*)

assertFalse(*expr*, *msg*=*None*)

Test that *expr* is true (or false).

Note that this is equivalent to `bool(expr) is True` and not to `expr is True` (use `assertIs(expr, True)` for the latter). This method should also be avoided when more specific methods are available (e.g. `assertEqual(a, b)` instead of `assertTrue(a == b)`), because they provide a better error message in case of failure.

assertIs(*first*, *second*, *msg*=*None*)

assertIsNot(*first*, *second*, *msg*=*None*)

Test that *first* and *second* are (or are not) the same object.

New in version 3.1.

assertIsNone(*expr*, *msg*=*None*)

assertIsNotNone(*expr*, *msg*=*None*)

Test that *expr* is (or is not) `None`.

New in version 3.1.

assertIn(*member*, *container*, *msg*=*None*)

assertNotIn(*member*, *container*, *msg*=*None*)

Test that *member* is (or is not) in *container*.

New in version 3.1.

assertIsInstance(*obj*, *cls*, *msg*=*None*)
assertNotIsInstance(*obj*, *cls*, *msg*=*None*)

Test that *obj* is (or is not) an instance of *cls* (which can be a class or a tuple of classes, as supported by `isinstance()`). To check for the exact type, use `assertIs(type(obj), cls)`.

New in version 3.2.

It is also possible to check the production of exceptions, warnings, and log messages using the following methods:

Method	Checks that
`assertRaises(exc, fun, *args, **kwds)`	`fun(*args, **kwds)` raises *exc*
`assertRaisesRegex(exc, r, fun, *args, **kwds)`	`fun(*args, **kwds)` raises *exc* and the message matches regex *r*
`assertWarns(warn, fun, *args, **kwds)`	`fun(*args, **kwds)` raises *warn*
`assertWarnsRegex(warn, r, fun, *args, **kwds)`	`fun(*args, **kwds)` raises *warn* and the message matches regex *r*
`assertLogs(logger, level)`	The `with` block logs on *logger* with minimum *level*
`assertNoLogs(logger, level)`	The `with` block does not log on *logger* with minimum *level*

assertRaises(*exception*, *callable*, **args*, ***kwds*)
assertRaises(*exception*, ***, *msg*=*None*)

Test that an exception is raised when *callable* is called with any positional or keyword arguments that are also passed to `assertRaises()`. The test passes if *exception* is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as *exception*.

If only the *exception* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertRaises(SomeException):
    do_something()
```

When used as a context manager, **assertRaises()** accepts the additional keyword argument *msg*.

The context manager will store the caught exception object in its **exception** attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```
with self.assertRaises(SomeException) as cm:
    do_something()

the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

Changed in version 3.1: Added the ability to use **assertRaises()** as a context manager.

Changed in version 3.2: Added the **exception** attribute.

Changed in version 3.3: Added the *msg* keyword argument when used as a context manager.

assertRaisesRegex(*exception*, *regex*, *callable*, **args*, ***kwds*)
assertRaisesRegex(*exception*, *regex*, ***, *msg=None*)

Like **assertRaises()** but also tests that *regex* matches on the string representation of the raised exception. *regex* may be a regular expression object or a string containing a regular expression suitable for use by **re.search()**. Examples:

```
self.assertRaisesRegex(ValueError, "invalid lit
                       int, 'XYZ')
```

or:

```
with self.assertRaisesRegex(ValueError, 'litera
   int('XYZ')
```

New in version 3.1: Added under the name

`assertRaisesRegexp`.

Changed in version 3.2: Renamed to **`assertRaisesRegex()`**.

Changed in version 3.3: Added the *msg* keyword argument when used as a context manager.

assertWarns(*warning*, *callable*, **args*, ***kwds*)
assertWarns(*warning*, ***, *msg=None*)

Test that a warning is triggered when *callable* is called with any positional or keyword arguments that are also passed to **`assertWarns()`**. The test passes if *warning* is triggered and fails if it isn't. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as *warnings*.

If only the *warning* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertWarns(SomeWarning):
    do_something()
```

When used as a context manager, **`assertWarns()`** accepts the additional keyword argument *msg*.

The context manager will store the caught warning object in its **`warning`** attribute, and the source line which triggered the warnings in the **`filename`** and **`lineno`** attributes. This can be useful if the intention is to perform additional checks on the warning caught:

```
with self.assertWarns(SomeWarning) as cm:
    do_something()

self.assertIn('myfile.py', cm.filename)
self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

New in version 3.2.

Changed in version 3.3: Added the *msg* keyword argument when used as a context manager.

assertWarnsRegex(*warning*, *regex*, *callable*, **args*, ***kwds*)

assertWarnsRegex(*warning*, *regex*, ***, *msg=None*)

Like **`assertWarns()`** but also tests that *regex* matches on the message of the triggered warning. *regex* may be a regular expression object or a string containing a regular expression suitable for use by **`re.search()`**. Example:

```
self.assertWarnsRegex(DeprecationWarning,
                      r'legacy_function\(\) is
                      legacy_function, 'XYZ')
```

or:

```
with self.assertWarnsRegex(RuntimeWarning, 'uns
    frobnicate('/etc/passwd')
```

New in version 3.2.

Changed in version 3.3: Added the *msg* keyword argument when used as a context manager.

assertLogs(*logger=None*, *level=None*)

A context manager to test that at least one message is logged on the *logger* or one of its children, with at least the given *level*.

If given, *logger* should be a **`logging.Logger`** object or a **`str`** giving the name of a logger. The default is the root logger, which will catch all messages that were not blocked by a non-propagating descendent logger.

If given, *level* should be either a numeric logging level or its string equivalent (for example either `"ERROR"` or **`logging.ERROR`**). The default is **`logging.INFO`**.

The test passes if at least one message emitted inside the `with` block matches the *logger* and *level* conditions, otherwise it fails.

The object returned by the context manager is a recording helper which keeps tracks of the matching log messages. It has two attributes:

records

A list of **`logging.LogRecord`** objects of the matching log messages.

output

A list of **`str`** objects with the formatted output of matching messages.

Example:

```
with self.assertLogs('foo', level='INFO') as cm
    logging.getLogger('foo').info('first messag
    logging.getLogger('foo.bar').error('second
self.assertEqual(cm.output, ['INFO:foo:first me
                             'ERROR:foo.bar:sec
```

New in version 3.4.

assertNoLogs(*logger*=*None*, *level*=*None*)

A context manager to test that no messages are logged on the *logger* or one of its children, with at least the given *level*.

If given, *logger* should be a **`logging.Logger`** object or a **`str`** giving the name of a logger. The default is the root logger, which will catch all messages.

If given, *level* should be either a numeric logging level

or its string equivalent (for example either `"ERROR"` or **`logging.ERROR`**). The default is **`logging.INFO`**.

Unlike **`assertLogs()`**, nothing will be returned by the context manager.

New in version 3.10.

There are also other methods used to perform more specific checks, such as:

Method	Checks that
`assertAlmostEqual(a, b)`	`round(a-b, 7) == 0`
`assertNotAlmostEqual(a, b)`	`round(a-b, 7) != 0`
`assertGreater(a, b)`	`a > b`
`assertGreaterEqual(a, b)`	`a >= b`
`assertLess(a, b)`	`a < b`
`assertLessEqual(a, b)`	`a <= b`
`assertRegex(s, r)`	`r.search(s)`
`assertNotRegex(s, r)`	`not r.search(s)`
`assertCountEqual(a, b)`	*a* and *b* have the same elements in the same number, regardless of their order.

assertAlmostEqual(*first*, *second*, *places* = *7*, *msg* = *None*, *delta* = *None*)

assertNotAlmostEqual(*first*, *second*, *places* = *7*, *msg* = *None*, *delta* = *None*)

Test that *first* and *second* are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal *places* (default 7), and comparing to zero. Note that these methods round the values to the given number of *decimal places* (i.e. like the **`round()`** function) and not *significant digits*.

If *delta* is supplied instead of *places* then the difference between *first* and *second* must be less or equal to (or greater than) *delta*.

Supplying both *delta* and *places* raises a **`TypeError`**.

Changed in version 3.2: **`assertAlmostEqual()`** automatically considers almost equal objects that compare equal. **`assertNotAlmostEqual()`** automatically fails if the objects compare equal. Added the *delta* keyword argument.

assertGreater(*first*, *second*, *msg*=*None*)

assertGreaterEqual(*first*, *second*, *msg*=*None*)

assertLess(*first*, *second*, *msg*=*None*)

assertLessEqual(*first*, *second*, *msg*=*None*)

Test that *first* is respectively >, >=, < or <= than *second* depending on the method name. If not, the test will fail:

```
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater th
```

New in version 3.1.

assertRegex(*text*, *regex*, *msg*=*None*)

assertNotRegex(*text*, *regex*, *msg*=*None*)

Test that a *regex* search matches (or does not match) *text*. In case of failure, the error message will include the pattern and the *text* (or the pattern and the part of *text* that unexpectedly matched). *regex* may be a regular expression object or a string containing a regular expression suitable for use by **`re.search()`**.

New in version 3.1: Added under the name `assertRegexpMatches`.

Changed in version 3.2: The method `assertRegexpMatches()` has been renamed to **`assertRegex()`**.

New in version 3.2: **`assertNotRegex()`**.

New in version 3.5: The name `assertNotRegexpMatches` is a deprecated alias for

assertNotRegex().

assertCountEqual(*first*, *second*, *msg*=*None*)

Test that sequence *first* contains the same elements as *second*, regardless of their order. When they don't, an error message listing the differences between the sequences will be generated.

Duplicate elements are *not* ignored when comparing *first* and *second*. It verifies whether each element has the same count in both sequences. Equivalent to: `assertEqual(Counter(list(first)), Counter(list(second)))` but works with sequences of unhashable objects as well.

New in version 3.2.

The **assertEqual()** method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using **addTypeEqualityFunc()**:

addTypeEqualityFunc(*typeobj*, *function*)

Registers a type-specific method called by **assertEqual()** to check if two objects of exactly the same *typeobj* (not subclasses) compare equal. *function* must take two positional arguments and a third msg=None keyword argument just as **assertEqual()** does. It must raise **self.failureException(msg)** when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.

New in version 3.1.

The list of type-specific methods automatically used by **assertEqual()** are summarized in the following table.

Note that it's usually not necessary to invoke these methods directly.

Method	compare
assertMultiLineEqual(a, b)	strings
assertSequenceEqual(a, b)	sequences
assertListEqual(a, b)	lists
assertTupleEqual(a, b)	tuples
assertSetEqual(a, b)	sets or frozensets
assertDictEqual(a, b)	dicts

assertMultiLineEqual(*first*, *second*, *msg*=*None*)

Test that the multiline string *first* is equal to the string *second*. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEqual()`.

New in version 3.1.

assertSequenceEqual(*first*, *second*, *msg*=*None*, *seq_type*=*None*)

Tests that two sequences are equal. If a *seq_type* is supplied, both *first* and *second* must be instances of *seq_type* or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by `assertEqual()`, but it's used to implement `assertListEqual()` and `assertTupleEqual()`.

New in version 3.1.

assertListEqual(*first*, *second*, *msg*=*None*)

assertTupleEqual(*first*, *second*, *msg*=*None*)

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are

used by default when comparing lists or tuples with **assertEqual()**.

New in version 3.1.

assertSetEqual(*first*, *second*, *msg*=*None*)

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with **assertEqual()**.

Fails if either of *first* or *second* does not have a **set.difference()** method.

New in version 3.1.

assertDictEqual(*first*, *second*, *msg*=*None*)

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to **assertEqual()**.

New in version 3.1.

Finally the **TestCase** provides the following methods and attributes:

fail(*msg*=*None*)

Signals a test failure unconditionally, with *msg* or `None` for the error message.

failureException

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to "play fair" with the framework. The initial value of this attribute is **AssertionError**.

longMessage

This class attribute determines what happens when a custom failure message is passed as the msg argument to an assertXYY call that fails. `True` is the default value. In this case, the custom message is appended to the end of the standard failure message. When set to `False`, the custom message replaces the standard message.

The class setting can be overridden in individual test methods by assigning an instance attribute, self.longMessage, to `True` or `False` before calling the assert methods.

The class setting gets reset before each test call.

New in version 3.1.

maxDiff

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80*8 characters. Assert methods affected by this attribute are **`assertSequenceEqual()`** (including all the sequence comparison methods that delegate to it), **`assertDictEqual()`** and **`assertMultiLineEqual()`**.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.

New in version 3.2.

Testing frameworks can use the following methods to collect information on the test:

countTestCases()

Return the number of tests represented by this test object. For **`TestCase`** instances, this will always be `1`.

defaultTestResult()

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the **`run()`** method).

For **`TestCase`** instances, this will always be an instance of **`TestResult`**; subclasses of **`TestCase`** should override this as necessary.

id()

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

shortDescription()

Returns a description of the test, or `None` if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or `None`.

Changed in version 3.1: In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the **`TextTestResult`** in Python 3.2.

addCleanup(*function*, */*, **args*, ***kwargs*)

Add a function to be called after **`tearDown()`** to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into **`addCleanup()`** when they are added.

If **`setUp()`** fails, meaning that **`tearDown()`** is not called, then any cleanup functions added will still be called.

New in version 3.1.

enterContext(*cm*)

Enter the supplied context manager. If successful, also add its **`__exit__()`** method as a cleanup function by **`addCleanup()`** and return the result of the **`__enter__()`** method.

New in version 3.11.

doCleanups()

This method is called unconditionally after **`tearDown()`**, or after **`setUp()`** if **`setUp()`** raises an exception.

It is responsible for calling all the cleanup functions added by **`addCleanup()`**. If you need cleanup functions to be called *prior* to **`tearDown()`** then you can call **`doCleanups()`** yourself.

`doCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

New in version 3.1.

classmethod addClassCleanup(*function*, */*, **args*, ***kwargs*)

Add a function to be called after **`tearDownClass()`** to cleanup resources used during the test class. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into **`addClassCleanup()`** when they are added.

If **`setUpClass()`** fails, meaning that **`tearDownClass()`** is not called, then any cleanup functions added will still be called.

New in version 3.8.

classmethod enterClassContext(*cm*)

Enter the supplied context manager. If successful, also add its **`__exit__()`** method as a cleanup function by **`addClassCleanup()`** and return the result of the **`__enter__()`** method.

New in version 3.11.

classmethod doClassCleanups()

This method is called unconditionally after **`tearDownClass()`**, or after **`setUpClass()`** if **`setUpClass()`** raises an exception.

It is responsible for calling all the cleanup functions added by **`addClassCleanup()`**. If you need cleanup functions to be called *prior* to **`tearDownClass()`** then you can call **`doClassCleanups()`** yourself.

`doClassCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

New in version 3.8.

class unittest.IsolatedAsyncioTestCase(*methodName='runTest'*)

This class provides an API similar to **`TestCase`** and also accepts coroutines as test functions.

New in version 3.8.

coroutine asyncSetUp()

Method called to prepare the test fixture. This is called after **`setUp()`**. This is called immediately before calling the test method; other than **`AssertionError`** or **`SkipTest`**, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

coroutine asyncTearDown()

Method called immediately after the test method has been called and the result recorded. This is called before **tearDown()**. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than **AssertionError** or **SkipTest**, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the **asyncSetUp()** succeeds, regardless of the outcome of the test method. The default implementation does nothing.

addAsyncCleanup(*function*, */*, **args*, ***kwargs*)

This method accepts a coroutine that can be used as a cleanup function.

coroutine enterAsyncContext(*cm*)

Enter the supplied asynchronous context manager. If successful, also add its **__aexit__()** method as a cleanup function by **addAsyncCleanup()** and return the result of the **__aenter__()** method.

New in version 3.11.

run(*result=None*)

Sets up a new event loop to run the test, collecting the result into the **TestResult** object passed as *result*. If *result* is omitted or `None`, a temporary result object is created (by calling the **defaultTestResult()** method) and used. The result object is returned to **run()**'s caller. At the end of the test all the tasks in the event loop are cancelled.

An example illustrating the order:

```
from unittest import IsolatedAsyncioTestCase
```

```
events = []

class Test(IsolatedAsyncioTestCase):

    def setUp(self):
        events.append("setUp")

    async def asyncSetUp(self):
        self._async_connection = await AsyncConnect
        events.append("asyncSetUp")

    async def test_response(self):
        events.append("test_response")
        response = await self._async_connection.get
        self.assertEqual(response.status_code, 200)
        self.addAsyncCleanup(self.on_cleanup)

    def tearDown(self):
        events.append("tearDown")

    async def asyncTearDown(self):
        await self._async_connection.close()
        events.append("asyncTearDown")

    async def on_cleanup(self):
        events.append("cleanup")

if __name__ == "__main__":
    unittest.main()
```

After running the test, `events` would contain `["setUp", "asyncSetUp", "test_response", "asyncTearDown", "tearDown", "cleanup"]`.

class unittest.FunctionTestCase(*testFunc*, *setUp=None*,

tearDown=*None*, *description*=*None*)

This class implements the portion of the **`TestCase`** interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a **`unittest`**-based test framework.

Deprecated aliases

For historical reasons, some of the **`TestCase`** methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:

Method Name	Deprecated aliases	Deprecated aliases
`assertEqual()`	failUnlessEqual	assertEquals
`assertNotEqual()`	failIfEqual	assertNotEquals
`assertTrue()`	failUnless	assert_
`assertFalse()`	failIf	
`assertRaises()`	failUnlessRaises	
`assertAlmostEqual()`	failUnlessAlmostEqual	assertAlmostEquals
`assertNotAlmostEqual()`	failIfAlmostEqual	assertNotAlmostEquals
`assertRegex()`		assertRegexpMatches
`assertNotRegex()`		assertNotRegexpMatches
`assertRaisesRegex()`		assertRaisesRegexp

Deprecated since version 3.1: The fail* aliases listed in the second column have been deprecated.

Deprecated since version 3.2: The assert* aliases listed in the third column have been deprecated.

Deprecated since version 3.2: `assertRegexpMatches` and `assertRaisesRegexp` have been renamed to **`assertRegex()`** and **`assertRaisesRegex()`**.

Deprecated since version 3.5: The `assertNotRegexpMatches` name is deprecated in favor of **`assertNotRegex()`**.

Grouping tests

class unittest.TestSuite(*tests* = *()*)

This class represents an aggregation of individual test cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a `TestSuite` instance is the same as iterating over the suite, running each test individually.

If *tests* is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

`TestSuite` objects behave much like `TestCase` objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to `TestSuite` instances:

addTest(*test*)

Add a `TestCase` or `TestSuite` to the suite.

addTests(*tests*)

Add all the tests from an iterable of `TestCase` and `TestSuite` instances to this test suite.

This is equivalent to iterating over *tests*, calling `addTest()` for each element.

`TestSuite` shares the following methods with `TestCase`:

run(*result*)

Run the tests associated with this suite, collecting the result into the test result object passed as *result*. Note that unlike `TestCase.run()`, `TestSuite.run()` requires the result object to be passed in.

debug()

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

countTestCases()

Return the number of tests represented by this test object, including all individual tests and sub-suites.

iter()

Tests grouped by a **TestSuite** are always accessed by iteration. Subclasses can lazily provide tests by overriding **__iter__()**. Note that this method may be called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned by repeated iterations before **TestSuite.run()** must be the same for each call iteration. After **TestSuite.run()**, callers should not rely on the tests returned by this method unless the caller uses a subclass that overrides **TestSuite._removeTestAtIndex()** to preserve test references.

Changed in version 3.2: In earlier versions the **TestSuite** accessed tests directly rather than through iteration, so overriding **__iter__()** wasn't sufficient for providing tests.

Changed in version 3.4: In earlier versions the **TestSuite** held references to each **TestCase** after **TestSuite.run()**. Subclasses can restore that behavior by overriding **TestSuite._removeTestAtIndex()**.

In the typical usage of a **TestSuite** object, the **run()** method is invoked by a **TestRunner** rather than by the end-user test harness.

Loading and running tests

class unittest.TestLoader

The **TestLoader** class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the **unittest** module provides an instance that can be shared as **unittest.defaultTestLoader**. Using a subclass or instance, however, allows customization of some configurable properties.

TestLoader objects have the following attributes:

errors

A list of the non-fatal errors encountered while loading tests. Not reset by the loader at any point. Fatal errors are signalled by the relevant method raising an exception to the caller. Non-fatal errors are also indicated by a synthetic test that will raise the original error when run.

New in version 3.5.

TestLoader objects have the following methods:

loadTestsFromTestCase(*testCaseClass*)

Return a suite of all test cases contained in the **TestCase**-derived **testCaseClass**.

A test case instance is created for each method named by **getTestCaseNames()**. By default these are the method names beginning with `test`. If **getTestCaseNames()** returns no methods, but the **runTest()** method is implemented, a single test case is created for that method instead.

loadTestsFromModule(*module*, *pattern*=*None*)

Return a suite of all test cases contained in the given module. This method searches *module* for classes

derived from **`TestCase`** and creates an instance of the class for each test method defined for the class.

Note

While using a hierarchy of **`TestCase`**-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the load_tests protocol. The *pattern* argument is passed as the third argument to `load_tests`.

Changed in version 3.2: Support for `load_tests` added.

Changed in version 3.5: The undocumented and unofficial *use_load_tests* default argument is deprecated and ignored, although it is still accepted for backward compatibility. The method also now accepts a keyword-only argument *pattern* which is passed to `load_tests` as the third argument.

loadTestsFromName(*name*, *module*=*None*)

Return a suite of all test cases given a string specifier.

The specifier *name* is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a **`TestSuite`** instance, or a callable object which returns a **`TestCase`** or **`TestSuite`** instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module **SampleTests** containing a **TestCase**-derived class **SampleTestCase** with three test methods (**test_one()**, **test_two()**, and **test_three()**), the specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the **test_two()** test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves *name* relative to the given *module*.

Changed in version 3.5: If an **ImportError** or **AttributeError** occurs while traversing *name* then a synthetic test that raises that error when run will be returned. These errors are included in the errors accumulated by self.errors.

loadTestsFromNames(*names*, *module*=*None*)

Similar to **loadTestsFromName()**, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

getTestCaseNames(*testCaseClass*)

Return a sorted sequence of method names found within *testCaseClass*; this should be a subclass of **TestCase**.

discover(*start_dir*, *pattern*='*test*.py*', *top_level_dir*=*None*)

Find all the test modules by recursing into subdirectories from the specified start directory, and return a TestSuite object containing them. Only test files that match *pattern* will be loaded. (Using shell style pattern matching.) Only module names that are

importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue. If the import failure is due to **SkipTest** being raised, it will be recorded as a skip instead of an error.

If a package (a directory containing a file named `__init__.py`) is found, the package will be checked for a `load_tests` function. If this exists then it will be called `package.load_tests(loader, tests, pattern)`. Test discovery takes care to ensure that a package is only checked for tests once during an invocation, even if the load_tests function itself calls `loader.discover`.

If `load_tests` exists then discovery does *not* recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. *top_level_dir* is stored so `load_tests` does not need to pass this argument in to `loader.discover()`.

start_dir can be a dotted module name as well as a directory.

New in version 3.2.

Changed in version 3.4: Modules that raise **SkipTest** on import are recorded as skips, not errors.

Changed in version 3.4: start_dir can be a namespace packages.

Changed in version 3.4: Paths are sorted before being imported so that execution order is the same even if the underlying file system's ordering is not dependent on file name.

Changed in version 3.5: Found packages are now checked for `load_tests` regardless of whether their path matches *pattern*, because it is impossible for a package name to match the default pattern.

Changed in version 3.11: start_dir can not be a namespace packages. It has been broken since Python 3.7 and Python 3.11 officially remove it.

The following attributes of a **`TestLoader`** can be configured either by subclassing or assignment on an instance:

testMethodPrefix

String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects **`getTestCaseNames()`** and all the **`loadTestsFrom*()`** methods.

sortTestMethodsUsing

Function to be used to compare method names when sorting them in **`getTestCaseNames()`** and all the **`loadTestsFrom*()`** methods.

suiteClass

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the **`TestSuite`** class.

This affects all the **`loadTestsFrom*()`** methods.

testNamePatterns

List of Unix shell-style wildcard test name patterns that test methods have to match to be included in test suites (see `-v` option).

If this attribute is not `None` (the default), all test methods to be included in test suites must match one of the patterns in this list. Note that matches are always performed using **`fnmatch.fnmatchcase()`**, so unlike patterns passed to the `-v` option, simple substring patterns will have to be converted using `*` wildcards.

This affects all the **`loadTestsFrom*()`** methods.

New in version 3.7.

class unittest.TestResult

This class is used to compile information about which tests have succeeded and which have failed.

A **`TestResult`** object stores the results of a set of tests. The **`TestCase`** and **`TestSuite`** classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of **`unittest`** may want access to the **`TestResult`** object generated by running a set of tests for reporting purposes; a **`TestResult`** instance is returned by the **`TestRunner.run()`** method for this purpose.

`TestResult` instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

errors

A list containing 2-tuples of **`TestCase`** instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

failures

A list containing 2-tuples of **TestCase** instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the **TestCase.assert*()** methods.

skipped

A list containing 2-tuples of **TestCase** instances and strings holding the reason for skipping the test.

New in version 3.1.

expectedFailures

A list containing 2-tuples of **TestCase** instances and strings holding formatted tracebacks. Each tuple represents an expected failure or error of the test case.

unexpectedSuccesses

A list containing **TestCase** instances that were marked as expected failures, but succeeded.

shouldStop

Set to `True` when the execution of tests should stop by **stop()**.

testsRun

The total number of tests run so far.

buffer

If set to true, `sys.stdout` and `sys.stderr` will be buffered in between **startTest()** and **stopTest()** being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

New in version 3.2.

failfast

If set to true **stop()** will be called on the first failure or error, halting the test run.

New in version 3.2.

tb_locals

If set to true then local variables will be shown in tracebacks.

New in version 3.5.

wasSuccessful()

Return `True` if all tests run so far have passed, otherwise returns `False`.

Changed in version 3.4: Returns `False` if there were any **unexpectedSuccesses** from tests marked with the **expectedFailure()** decorator.

stop()

This method can be called to signal that the set of tests being run should be aborted by setting the **shouldStop** attribute to `True`. **TestRunner** objects should respect this flag and return without running any additional tests.

For example, this feature is used by the **TextTestRunner** class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide **TestRunner** implementations can use this in a similar manner.

The following methods of the **TestResult** class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

startTest(*test*)

Called when the test case *test* is about to be run.

stopTest(*test*)

Called after the test case *test* has been executed, regardless of the outcome.

startTestRun()

Called once before any tests are executed.

New in version 3.1.

stopTestRun()

Called once after all tests are executed.

New in version 3.1.

addError(*test*, *err*)

Called when the test case *test* raises an unexpected exception. *err* is a tuple of the form returned by **`sys.exc_info()`**: `(type, value, traceback)`.

The default implementation appends a tuple `(test, formatted_err)` to the instance's **`errors`** attribute, where *formatted_err* is a formatted traceback derived from *err*.

addFailure(*test*, *err*)

Called when the test case *test* signals a failure. *err* is a tuple of the form returned by **`sys.exc_info()`**: `(type, value, traceback)`.

The default implementation appends a tuple `(test, formatted_err)` to the instance's **`failures`** attribute, where *formatted_err* is a formatted traceback derived from *err*.

addSuccess(*test*)

Called when the test case *test* succeeds.

The default implementation does nothing.

addSkip(*test*, *reason*)

Called when the test case *test* is skipped. *reason* is the reason the test gave for skipping.

The default implementation appends a tuple `(test, reason)` to the instance's **`skipped`** attribute.

addExpectedFailure(*test*, *err*)

Called when the test case *test* fails or errors, but was marked with the **`expectedFailure()`** decorator.

The default implementation appends a tuple `(test, formatted_err)` to the instance's **`expectedFailures`** attribute, where *formatted_err* is a formatted traceback derived from *err*.

addUnexpectedSuccess(*test*)

Called when the test case *test* was marked with the **`expectedFailure()`** decorator, but succeeded.

The default implementation appends the test to the instance's **`unexpectedSuccesses`** attribute.

addSubTest(*test*, *subtest*, *outcome*)

Called when a subtest finishes. *test* is the test case corresponding to the test method. *subtest* is a custom **`TestCase`** instance describing the subtest.

If *outcome* is **`None`**, the subtest succeeded. Otherwise, it failed with an exception where *outcome* is a tuple of the form returned by **`sys.exc_info()`**: `(type, value, traceback)`.

The default implementation does nothing when the outcome is a success, and records subtest failures as normal failures.

New in version 3.4.

class unittest.TextTestResult(*stream*, *descriptions*, *verbosity*)

A concrete implementation of **TestResult** used by the **TextTestRunner**.

New in version 3.2: This class was previously named `_TextTestResult`. The old name still exists as an alias but is deprecated.

unittest.defaultTestLoader

Instance of the **TestLoader** class intended to be shared. If no customization of the **TestLoader** is needed, this instance can be used instead of repeatedly creating new instances.

class unittest.TextTestRunner(*stream=None*, *descriptions=True*, *verbosity=1*, *failfast=False*, *buffer=False*, *resultclass=None*, *warnings=None*, ***, *tb_locals=False*)

A basic test runner implementation that outputs results to a stream. If *stream* is `None`, the default, **sys.stderr** is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations. Such implementations should accept `**kwargs` as the interface to construct runners changes when features are added to unittest.

By default this runner shows **DeprecationWarning**, **PendingDeprecationWarning**, **ResourceWarning** and **ImportWarning** even if they are ignored by default. Deprecation warnings caused by deprecated unittest methods are also special-cased and, when the warning filters are `'default'` or `'always'`, they will appear only once per-module, in order to avoid too many warning messages. This behavior can be overridden using Python's **-Wd** or **-Wa**

options (see Warning control) and leaving *warnings* to `None`.

Changed in version 3.2: Added the `warnings` argument.

Changed in version 3.2: The default stream is set to **`sys.stderr`** at instantiation time rather than import time.

Changed in version 3.5: Added the tb_locals parameter.

_makeResult()

This method returns the instance of `TestResult` used by **`run()`**. It is not intended to be called directly, but can be overridden in subclasses to provide a custom `TestResult`.

`_makeResult()` instantiates the class or callable passed in the `TextTestRunner` constructor as the `resultclass` argument. It defaults to **`TextTestResult`** if no `resultclass` is provided. The result class is instantiated with the following arguments:

```
stream, descriptions, verbosity
```

run(*test*)

This method is the main public interface to the `TextTestRunner`. This method takes a **`TestSuite`** or **`TestCase`** instance. A **`TestResult`** is created by calling **`_makeResult()`** and the test(s) are run and the results printed to stdout.

unittest.main(*module='_main_', defaultTest=None, argv=None, testRunner=None, testLoader=unittest.defaultTestLoader, exit=True, verbosity=1, failfast=None, catchbreak=None, buffer=None, warnings=None*)

A command-line program that loads a set of tests from *module* and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

```
if __name__ == '__main__':
    unittest.main()
```

You can run tests with more detailed information by passing in the verbosity argument:

```
if __name__ == '__main__':
    unittest.main(verbosity=2)
```

The *defaultTest* argument is either the name of a single test or an iterable of test names to run if no test names are specified via *argv*. If not specified or `None` and no test names are provided via *argv*, all tests found in *module* are run.

The *argv* argument can be a list of options passed to the program, with the first element being the program name. If not specified or `None`, the values of **`sys.argv`** are used.

The *testRunner* argument can either be a test runner class or an already created instance of it. By default `main` calls **`sys.exit()`** with an exit code indicating success or failure of the tests run.

The *testLoader* argument has to be a **`TestLoader`** instance, and defaults to **`defaultTestLoader`**.

`main` supports being used from the interactive interpreter by passing in the argument `exit=False`. This displays the result on standard output without calling **`sys.exit()`**:

```
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The *failfast*, *catchbreak* and *buffer* parameters have the same effect as the same-name command-line options.

The *warnings* argument specifies the warning filter that should be used while running the tests. If it's not specified, it will remain `None` if a **`-W`** option is passed to **python** (see Warning control), otherwise it will be set to `'default'`.

Calling `main` actually returns an instance of the

`TestProgram` class. This stores the result of the tests run as the `result` attribute.

Changed in version 3.1: The *exit* parameter was added.

Changed in version 3.2: The *verbosity*, *failfast*, *catchbreak*, *buffer* and *warnings* parameters were added.

Changed in version 3.4: The *defaultTest* parameter was changed to also accept an iterable of test names.

load_tests Protocol

New in version 3.2.

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called `load_tests`.

If a test module defines `load_tests` it will be called by **`TestLoader.loadTestsFromModule()`** with the following arguments:

```
load_tests(loader, standard_tests, pattern)
```

where *pattern* is passed straight through from `loadTestsFromModule`. It defaults to `None`.

It should return a **`TestSuite`**.

loader is the instance of **`TestLoader`** doing the loading. *standard_tests* are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical `load_tests` function that loads tests from a specific set of **`TestCase`** classes may look like:

```
test_cases = (TestCase1, TestCase2, TestCase3)
```

```
def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite
```

If discovery is started in a directory containing a package, either from the command line or by calling **`TestLoader.discover()`**, then the package `__init__.py` will be checked for `load_tests`. If that function does not exist, discovery will recurse into the package as though it were just another directory. Otherwise, discovery of the package's tests will be left up to `load_tests` which is called with the following arguments:

```
load_tests(loader, standard_tests, pattern)
```

This should return a **`TestSuite`** representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A 'do nothing' `load_tests` function for a test package would look like:

```
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir,
    standard_tests.addTests(package_tests)
    return standard_tests
```

Changed in version 3.5: Discovery no longer checks package names for matching *pattern* due to the impossibility of package names matching the default pattern.

Class and Module Fixtures

Class and module level fixtures are implemented in **`TestSuite`**. When the test suite encounters a test from a new class then

`tearDownClass()` from the previous class (if there is one) is called, followed by **`setUpClass()`** from the new class.

Similarly if a test is from a different module from the previous test then `tearDownModule` from the previous module is run, followed by `setUpModule` from the new module.

After all the tests have run the final `tearDownClass` and `tearDownModule` are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to `setUpClass / setUpModule` (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A `BaseTestSuite` still exists for frameworks that don't want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no corresponding test instance an `_ErrorHolder` object (that has the same interface as a **`TestCase`**) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn't matter, but if you are a framework author it may be relevant.

setUpClass and tearDownClass

These must be implemented as class methods:

```
import unittest

class Test(unittest.TestCase):
```

```
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObjec

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the `setUpClass` and `tearDownClass` on base classes called then you must call up to them yourself. The implementations in **`TestCase`** are empty.

If an exception is raised during a `setUpClass` then the tests in the class are not run and the `tearDownClass` is not run. Skipped classes will not have `setUpClass` or `tearDownClass` run. If the exception is a **`SkipTest`** exception then the class will be reported as having been skipped instead of as an error.

setUpModule and tearDownModule

These should be implemented as functions:

```
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a **`SkipTest`** exception then the module will be reported as having been skipped instead of as an error.

To add cleanup code that must be run even in the case of an exception, use `addModuleCleanup`:

unittest.addModuleCleanup(*function*, */*, **args*, ***kwargs*)

> Add a function to be called after **`tearDownModule()`** to cleanup resources used during the test class. Functions will be called in reverse order to the order they are added (LIFO).

They are called with any arguments and keyword arguments passed into **addModuleCleanup()** when they are added.

If **setUpModule()** fails, meaning that **tearDownModule()** is not called, then any cleanup functions added will still be called.

New in version 3.8.

classmethod unittest.enterModuleContext(*cm*)

Enter the supplied context manager. If successful, also add its **__exit__()** method as a cleanup function by **addModuleCleanup()** and return the result of the **__enter__()** method.

New in version 3.11.

unittest.doModuleCleanups()

This function is called unconditionally after **tearDownModule()**, or after **setUpModule()** if **setUpModule()** raises an exception.

It is responsible for calling all the cleanup functions added by **addModuleCleanup()**. If you need cleanup functions to be called *prior* to **tearDownModule()** then you can call **doModuleCleanups()** yourself.

doModuleCleanups() pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

New in version 3.8.

Signal Handling

New in version 3.2.

The **-c/--catch** command-line option to unittest, along with the `catchbreak` parameter to **unittest.main()**, provide more

friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a **`KeyboardInterrupt`** in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own **`signal.SIGINT`** handler. If the `unittest` handler is called but *isn't* the installed **`signal.SIGINT`** handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need `unittest` control-c handling disabled the **`removeHandler()`** decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

unittest.installHandler()

> Install the control-c handler. When a **`signal.SIGINT`** is received (usually in response to the user pressing control-c) all registered results have **`stop()`** called.

unittest.registerResult(*result*)

> Register a **`TestResult`** object for control-c handling. Registering a result stores a weak reference to it, so it doesn't prevent the result from being garbage collected.
>
> Registering a **`TestResult`** object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

unittest.removeResult(*result*)

> Remove a registered result. Once a result has been removed then **`stop()`** will no longer be called on that result object in response to a control-c.

unittest.removeHandler(*function=None*)

When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler while the test is being executed:

```
@unittest.removeHandler
def test_signal_handling(self):
    ...
```

`unittest.mock` — mock object library

New in version 3.3.

Source code: Lib/unittest/mock.py [https://github.com/python/cpython/tree/3.11/Lib/unittest/mock.py]

`unittest.mock` is a library for testing in Python. It allows you to replace parts of your system under test with mock objects and make assertions about how they have been used.

`unittest.mock` provides a core `Mock` class removing the need to create a host of stubs throughout your test suite. After performing an action, you can make assertions about which methods / attributes were used and arguments they were called with. You can also specify return values and set needed attributes in the normal way.

Additionally, mock provides a `patch()` decorator that handles patching module and class level attributes within the scope of a test, along with `sentinel` for creating unique objects. See the quick guide for some examples of how to use `Mock`, `MagicMock` and `patch()`.

Mock is designed for use with `unittest` and is based on the 'action -> assertion' pattern instead of 'record -> replay' used by many mocking frameworks.

There is a backport of `unittest.mock` for earlier versions of Python, available as mock on PyPI [https://pypi.org/project/mock].

Quick Guide

`Mock` and `MagicMock` objects create all attributes and methods as

you access them and store details of how they have been used. You can configure them, to specify return values or limit what attributes are available, and then make assertions about how they have been used:

```
>>> from unittest.mock import MagicMock
>>> thing = ProductionClass()
>>> thing.method = MagicMock(return_value=3)
>>> thing.method(3, 4, 5, key='value')
3
>>> thing.method.assert_called_with(3, 4, 5, key='value'
```

`side_effect` allows you to perform side effects, including raising an exception when a mock is called:

```
>>> mock = Mock(side_effect=KeyError('foo'))
>>> mock()
Traceback (most recent call last):
 ...
KeyError: 'foo'

>>> values = {'a': 1, 'b': 2, 'c': 3}
>>> def side_effect(arg):
...     return values[arg]
...
>>> mock.side_effect = side_effect
>>> mock('a'), mock('b'), mock('c')
(1, 2, 3)
>>> mock.side_effect = [5, 4, 3, 2, 1]
>>> mock(), mock(), mock()
(5, 4, 3)
```

Mock has many other ways you can configure it and control its behaviour. For example the *spec* argument configures the mock to take its specification from another object. Attempting to access attributes or methods on the mock that don't exist on the spec will fail with an **`AttributeError`**.

The **`patch()`** decorator / context manager makes it easy to mock classes or objects in a module under test. The object you specify will

be replaced with a mock (or other object) during the test and restored when the test ends:

```
>>> from unittest.mock import patch
>>> @patch('module.ClassName2')
... @patch('module.ClassName1')
... def test(MockClass1, MockClass2):
...     module.ClassName1()
...     module.ClassName2()
...     assert MockClass1 is module.ClassName1
...     assert MockClass2 is module.ClassName2
...     assert MockClass1.called
...     assert MockClass2.called
...
>>> test()
```

Note

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal *Python* order that decorators are applied). This means from the bottom up, so in the example above the mock for `module.ClassName1` is passed in first.

With **`patch()`** it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read where to patch.

As well as a decorator **`patch()`** can be used as a context manager in a with statement:

```
>>> with patch.object(ProductionClass, 'method', return_
...     thing = ProductionClass()
...     thing.method(1, 2, 3)
...
>>> mock_method.assert_called_once_with(1, 2, 3)
```

There is also **`patch.dict()`** for setting values in a dictionary just during a scope and restoring the dictionary to its original state

when the test ends:

```
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=T
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

Mock supports the mocking of Python magic methods. The easiest way of using magic methods is with the **`MagicMock`** class. It allows you to do things like:

```
>>> mock = MagicMock()
>>> mock.__str__.return_value = 'foobarbaz'
>>> str(mock)
'foobarbaz'
>>> mock.__str__.assert_called_with()
```

Mock allows you to assign functions (or other Mock instances) to magic methods and they will be called appropriately. The **`MagicMock`** class is just a Mock variant that has all of the magic methods pre-created for you (well, all the useful ones anyway).

The following is an example of using magic methods with the ordinary Mock class:

```
>>> mock = Mock()
>>> mock.__str__ = Mock(return_value='wheeeeee')
>>> str(mock)
'wheeeeee'
```

For ensuring that the mock objects in your tests have the same api as the objects they are replacing, you can use auto-speccing. Auto-speccing can be done through the *autospec* argument to patch, or the **`create_autospec()`** function. Auto-speccing creates mock objects that have the same attributes and methods as the objects they are replacing, and any functions and methods (including constructors) have the same call signature as the real object.

This ensures that your mocks will fail in the same way as your

production code if they are used incorrectly:

```
>>> from unittest.mock import create_autospec
>>> def function(a, b, c):
...     pass
...
>>> mock_function = create_autospec(function, return_val
>>> mock_function(1, 2, 3)
'fishy'
>>> mock_function.assert_called_once_with(1, 2, 3)
>>> mock_function('wrong arguments')
Traceback (most recent call last):
 ...
TypeError: <lambda>() takes exactly 3 arguments (1 giver
```

create_autospec() can also be used on classes, where it copies the signature of the `__init__` method, and on callable objects where it copies the signature of the `__call__` method.

The Mock Class

Mock is a flexible mock object intended to replace the use of stubs and test doubles throughout your code. Mocks are callable and create attributes as new mocks when you access them 1. Accessing the same attribute will always return the same mock. Mocks record how you use them, allowing you to make assertions about what your code has done to them.

MagicMock is a subclass of **Mock** with all the magic methods pre-created and ready to use. There are also non-callable variants, useful when you are mocking out objects that aren't callable: **NonCallableMock** and **NonCallableMagicMock**

The **patch()** decorators makes it easy to temporarily replace classes in a particular module with a **Mock** object. By default **patch()** will create a **MagicMock** for you. You can specify an alternative class of **Mock** using the *new_callable* argument to **patch()**.

class unittest.mock.Mock(*spec*=*None*, *side_effect*=*None*,

return_value=*DEFAULT*, *wraps*=*None*, *name*=*None*, *spec_set*=*None*, *unsafe*=*False*, ***kwargs*)

Create a new **Mock** object. **Mock** takes several optional arguments that specify the behaviour of the Mock object:

- *spec*: This can be either a list of strings or an existing object (a class or instance) that acts as the specification for the mock object. If you pass in an object then a list of strings is formed by calling dir on the object (excluding unsupported magic attributes and methods). Accessing any attribute not in this list will raise an **AttributeError**.

  If *spec* is an object (rather than a list of strings) then **__class__** returns the class of the spec object. This allows mocks to pass **isinstance()** tests.

- *spec_set*: A stricter variant of *spec*. If used, attempting to *set* or get an attribute on the mock that isn't on the object passed as *spec_set* will raise an **AttributeError**.

- *side_effect*: A function to be called whenever the Mock is called. See the **side_effect** attribute. Useful for raising exceptions or dynamically changing return values. The function is called with the same arguments as the mock, and unless it returns **DEFAULT**, the return value of this function is used as the return value.

  Alternatively *side_effect* can be an exception class or instance. In this case the exception will be raised when the mock is called.

  If *side_effect* is an iterable then each call to the mock will return the next value from the iterable.

  A *side_effect* can be cleared by setting it to `None`.

- *return_value*: The value returned when the mock is called. By default this is a new Mock (created on first access). See the **return_value** attribute.

- *unsafe*: By default, accessing any attribute whose name starts with *assert*, *assret*, *asert*, *aseert* or *assrt* will raise an **AttributeError**. Passing `unsafe=True` will allow access to these attributes.

  New in version 3.5.

- *wraps*: Item for the mock object to wrap. If *wraps* is not `None` then calling the Mock will pass the call through to the wrapped object (returning the real result). Attribute access on the mock will return a Mock object that wraps the corresponding attribute of the wrapped object (so attempting to access an attribute that doesn't exist will raise an **AttributeError**).

  If the mock has an explicit *return_value* set then calls are not passed to the wrapped object and the *return_value* is returned instead.

- *name*: If the mock has a name then it will be used in the repr of the mock. This can be useful for debugging. The name is propagated to child mocks.

Mocks can also be called with arbitrary keyword arguments. These will be used to set attributes on the mock after it is created. See the **configure_mock()** method for details.

assert_called()

Assert that the mock was called at least once.

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called()
```

New in version 3.6.

assert_called_once()

Assert that the mock was called exactly once.

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_once()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_once()
Traceback (most recent call last):
...
AssertionError: Expected 'method' to have been
```

New in version 3.6.

assert_called_with(**args*, ***kwargs*)

This method is a convenient way of asserting that the last call has been made in a particular way:

```
>>> mock = Mock()
>>> mock.method(1, 2, 3, test='wow')
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_with(1, 2, 3, tes
```

assert_called_once_with(**args*, ***kwargs*)

Assert that the mock was called exactly once and that call was with the specified arguments.

```
>>> mock = Mock(return_value=None)
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='ba
>>> mock('other', bar='values')
>>> mock.assert_called_once_with('other', bar='
Traceback (most recent call last):
  ...
AssertionError: Expected 'mock' to be called or
```

assert_any_call(**args*, ***kwargs*)

assert the mock has been called with the specified arguments.

The assert passes if the mock has *ever* been called, unlike **assert_called_with()** and **assert_called_once_with()** that only pass if the call is the most recent one, and in the case of **assert_called_once_with()** it must also be the only call.

```
>>> mock = Mock(return_value=None)
>>> mock(1, 2, arg='thing')
>>> mock('some', 'thing', 'else')
>>> mock.assert_any_call(1, 2, arg='thing')
```

assert_has_calls(*calls*, *any_order*=*False*)

assert the mock has been called with the specified calls. The **mock_calls** list is checked for the calls.

If *any_order* is false then the calls must be sequential. There can be extra calls before or after the specified calls.

If *any_order* is true then the calls can be in any order, but they must all appear in **mock_calls**.

```
>>> mock = Mock(return_value=None)
>>> mock(1)
>>> mock(2)
>>> mock(3)
>>> mock(4)
>>> calls = [call(2), call(3)]
>>> mock.assert_has_calls(calls)
>>> calls = [call(4), call(2), call(3)]
>>> mock.assert_has_calls(calls, any_order=True
```

assert_not_called()

Assert the mock was never called.

```
>>> m = Mock()
>>> m.hello.assert_not_called()
>>> obj = m.hello()
```

```
>>> m.hello.assert_not_called()
Traceback (most recent call last):
  ...
AssertionError: Expected 'hello' to not have be
```

New in version 3.5.

reset_mock(*, *return_value=False*, *side_effect=False*)

The reset_mock method resets all the call attributes on a mock object:

```
>>> mock = Mock(return_value=None)
>>> mock('hello')
>>> mock.called
True
>>> mock.reset_mock()
>>> mock.called
False
```

Changed in version 3.6: Added two keyword only argument to the reset_mock function.

This can be useful where you want to make a series of assertions that reuse the same object. Note that **`reset_mock()`** *doesn't* clear the return value, **`side_effect`** or any child attributes you have set using normal assignment by default. In case you want to reset *return_value* or **`side_effect`**, then pass the corresponding parameter as `True`. Child mocks and the return value mock (if any) are reset as well.

Note

return_value, and **`side_effect`** are keyword only argument.

mock_add_spec(*spec*, *spec_set=False*)

Add a spec to a mock. *spec* can either be an object or a

list of strings. Only attributes on the *spec* can be fetched as attributes from the mock.

If *spec_set* is true then only attributes on the spec can be set.

attach_mock(*mock*, *attribute*)

Attach a mock as an attribute of this one, replacing its name and parent. Calls to the attached mock will be recorded in the **method_calls** and **mock_calls** attributes of this one.

configure_mock(***kwargs*)

Set attributes on the mock through keyword arguments.

Attributes plus return values and side effects can be set on child mocks using standard dot notation and unpacking a dictionary in the method call:

```
>>> mock = Mock()
>>> attrs = {'method.return_value': 3, 'other.s
>>> mock.configure_mock(**attrs)
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ...
KeyError
```

The same thing can be achieved in the constructor call to mocks:

```
>>> attrs = {'method.return_value': 3, 'other.s
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
```

```
Traceback (most recent call last):
  ...
KeyError
```

configure_mock() exists to make it easier to do configuration after the mock has been created.

dir()

Mock objects limit the results of `dir(some_mock)` to useful results. For mocks with a *spec* this includes all the permitted attributes for the mock.

See **FILTER_DIR** for what this filtering does, and how to switch it off.

_get_child_mock(***kw*)

Create the child mocks for attributes and return value. By default child mocks will be the same type as the parent. Subclasses of Mock may want to override this to customize the way child mocks are made.

For non-callable mocks the callable variant will be used (rather than any custom subclass).

called

A boolean representing whether or not the mock object has been called:

```
>>> mock = Mock(return_value=None)
>>> mock.called
False
>>> mock()
>>> mock.called
True
```

call_count

An integer telling you how many times the mock object has been called:

```
>>> mock = Mock(return_value=None)
>>> mock.call_count
0
>>> mock()
>>> mock()
>>> mock.call_count
2
```

return_value

Set this to configure the value returned by calling the mock:

```
>>> mock = Mock()
>>> mock.return_value = 'fish'
>>> mock()
'fish'
```

The default return value is a mock object and you can configure it in the normal way:

```
>>> mock = Mock()
>>> mock.return_value.attribute = sentinel.Attr
>>> mock.return_value()
<Mock name='mock()()' id='...'>
>>> mock.return_value.assert_called_with()
```

return_value can also be set in the constructor:

```
>>> mock = Mock(return_value=3)
>>> mock.return_value
3
>>> mock()
3
```

side_effect

This can either be a function to be called when the mock is called, an iterable or an exception (class or instance) to be raised.

If you pass in a function it will be called with same arguments as the mock and unless the function returns the **DEFAULT** singleton the call to the mock will then return whatever the function returns. If the function returns **DEFAULT** then the mock will return its normal value (from the **return_value**).

If you pass in an iterable, it is used to retrieve an iterator which must yield a value on every call. This value can either be an exception instance to be raised, or a value to be returned from the call to the mock (**DEFAULT** handling is identical to the function case).

An example of a mock that raises an exception (to test exception handling of an API):

```
>>> mock = Mock()
>>> mock.side_effect = Exception('Boom!')
>>> mock()
Traceback (most recent call last):
  ...
Exception: Boom!
```

Using **side_effect** to return a sequence of values:

```
>>> mock = Mock()
>>> mock.side_effect = [3, 2, 1]
>>> mock(), mock(), mock()
(3, 2, 1)
```

Using a callable:

```
>>> mock = Mock(return_value=3)
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> mock.side_effect = side_effect
>>> mock()
3
```

side_effect can be set in the constructor. Here's an

example that adds one to the value the mock is called with and returns it:

```
>>> side_effect = lambda value: value + 1
>>> mock = Mock(side_effect=side_effect)
>>> mock(3)
4
>>> mock(-8)
-7
```

Setting **side_effect** to `None` clears it:

```
>>> m = Mock(side_effect=KeyError, return_value
>>> m()
Traceback (most recent call last):
 ...
KeyError
>>> m.side_effect = None
>>> m()
3
```

call_args

This is either `None` (if the mock hasn't been called), or the arguments that the mock was last called with. This will be in the form of a tuple: the first member, which can also be accessed through the `args` property, is any ordered arguments the mock was called with (or an empty tuple) and the second member, which can also be accessed through the `kwargs` property, is any keyword arguments (or an empty dictionary).

```
>>> mock = Mock(return_value=None)
>>> print(mock.call_args)
None
>>> mock()
>>> mock.call_args
call()
>>> mock.call_args == ()
True
```

```
>>> mock(3, 4)
>>> mock.call_args
call(3, 4)
>>> mock.call_args == ((3, 4),)
True
>>> mock.call_args.args
(3, 4)
>>> mock.call_args.kwargs
{}
>>> mock(3, 4, 5, key='fish', next='w00t!')
>>> mock.call_args
call(3, 4, 5, key='fish', next='w00t!')
>>> mock.call_args.args
(3, 4, 5)
>>> mock.call_args.kwargs
{'key': 'fish', 'next': 'w00t!'}
```

call_args, along with members of the lists **call_args_list**, **method_calls** and **mock_calls** are **call** objects. These are tuples, so they can be unpacked to get at the individual arguments and make more complex assertions. See calls as tuples.

Changed in version 3.8: Added `args` and `kwargs` properties.

call_args_list

This is a list of all the calls made to the mock object in sequence (so the length of the list is the number of times it has been called). Before any calls have been made it is an empty list. The **call** object can be used for conveniently constructing lists of calls to compare with **call_args_list**.

```
>>> mock = Mock(return_value=None)
>>> mock()
>>> mock(3, 4)
>>> mock(key='fish', next='w00t!')
```

```
>>> mock.call_args_list
[call(), call(3, 4), call(key='fish', next='w00
>>> expected = [(), ((3, 4),), ({'key': 'fish',
>>> mock.call_args_list == expected
True
```

Members of **`call_args_list`** are **`call`** objects. These can be unpacked as tuples to get at the individual arguments. See calls as tuples.

method_calls

As well as tracking calls to themselves, mocks also track calls to methods and attributes, and *their* methods and attributes:

```
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.property.method.attribute()
<Mock name='mock.property.method.attribute()' i
>>> mock.method_calls
[call.method(), call.property.method.attribute
```

Members of **`method_calls`** are **`call`** objects. These can be unpacked as tuples to get at the individual arguments. See calls as tuples.

mock_calls

`mock_calls` records *all* calls to the mock object, its methods, magic methods *and* return value mocks.

```
>>> mock = MagicMock()
>>> result = mock(1, 2, 3)
>>> mock.first(a=3)
<MagicMock name='mock.first()' id='...'>
>>> mock.second()
<MagicMock name='mock.second()' id='...'>
>>> int(mock)
1
```

```
>>> result(1)
<MagicMock name='mock()()' id='...'>
>>> expected = [call(1, 2, 3), call.first(a=3),
... call.__int__(), call()(1)]
>>> mock.mock_calls == expected
True
```

Members of **mock_calls** are **call** objects. These can be unpacked as tuples to get at the individual arguments. See calls as tuples.

Note

The way **mock_calls** are recorded means that where nested calls are made, the parameters of ancestor calls are not recorded and so will always compare equal:

```
>>> mock = MagicMock()
>>> mock.top(a=3).bottom()
<MagicMock name='mock.top().bottom()' id='...'
>>> mock.mock_calls
[call.top(a=3), call.top().bottom()]
>>> mock.mock_calls[-1] == call.top(a=-1).bott
True
```

class

Normally the **__class__** attribute of an object will return its type. For a mock object with a **spec**, `__class__` returns the spec class instead. This allows mock objects to pass **isinstance()** tests for the object they are replacing / masquerading as:

```
>>> mock = Mock(spec=3)
>>> isinstance(mock, int)
True
```

__class__ is assignable to, this allows a mock to pass

an **isinstance()** check without forcing you to use a spec:

```
>>> mock = Mock()
>>> mock.__class__ = dict
>>> isinstance(mock, dict)
True
```

class unittest.mock.NonCallableMock(*spec=None*, *wraps=None*, *name=None*, *spec_set=None*, ***kwargs*)

A non-callable version of **Mock**. The constructor parameters have the same meaning of **Mock**, with the exception of *return_value* and *side_effect* which have no meaning on a non-callable mock.

Mock objects that use a class or an instance as a **spec** or **spec_set** are able to pass **isinstance()** tests:

```
>>> mock = Mock(spec=SomeClass)
>>> isinstance(mock, SomeClass)
True
>>> mock = Mock(spec_set=SomeClass())
>>> isinstance(mock, SomeClass)
True
```

The **Mock** classes have support for mocking magic methods. See magic methods for the full details.

The mock classes and the **patch()** decorators all take arbitrary keyword arguments for configuration. For the **patch()** decorators the keywords are passed to the constructor of the mock being created. The keyword arguments are for configuring attributes of the mock:

```
>>> m = MagicMock(attribute=3, other='fish')
>>> m.attribute
3
>>> m.other
'fish'
```

The return value and side effect of child mocks can be set in the same way, using dotted notation. As you can't use dotted names directly in a call you have to create a dictionary and unpack it using **:

```
>>> attrs = {'method.return_value': 3, 'other.side_effec
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ...
KeyError
```

A callable mock which was created with a *spec* (or a *spec_set*) will introspect the specification object's signature when matching calls to the mock. Therefore, it can match the actual call's arguments regardless of whether they were passed positionally or by name:

```
>>> def f(a, b, c): pass
...
>>> mock = Mock(spec=f)
>>> mock(1, 2, c=3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(1, 2, 3)
>>> mock.assert_called_with(a=1, b=2, c=3)
```

This applies to **`assert_called_with()`**, **`assert_called_once_with()`**, **`assert_has_calls()`** and **`assert_any_call()`**. When Autospeccing, it will also apply to method calls on the mock object.

> *Changed in version 3.4:* Added signature introspection on specced and autospecced mock objects.

class unittest.mock.PropertyMock(**args*, ***kwargs*)

A mock intended to be used as a property, or other descriptor,

on a class. **PropertyMock** provides **__get__()** and **__set__()** methods so you can specify a return value when it is fetched.

Fetching a **PropertyMock** instance from an object calls the mock, with no args. Setting it calls the mock with the value being set.

```
>>> class Foo:
...     @property
...     def foo(self):
...         return 'something'
...     @foo.setter
...     def foo(self, value):
...         pass
...
>>> with patch('__main__.Foo.foo', new_callable=Pro
...     mock_foo.return_value = 'mockity-mock'
...     this_foo = Foo()
...     print(this_foo.foo)
...     this_foo.foo = 6
...
mockity-mock
>>> mock_foo.mock_calls
[call(), call(6)]
```

Because of the way mock attributes are stored you can't directly attach a **PropertyMock** to a mock object. Instead you can attach it to the mock type object:

```
>>> m = MagicMock()
>>> p = PropertyMock(return_value=3)
>>> type(m).foo = p
>>> m.foo
3
>>> p.assert_called_once_with()
```

class unittest.mock.AsyncMock(*spec=None*, *side_effect=None*, *return_value=DEFAULT*, *wraps=None*, *name=None*, *spec_set=None*,

unsafe=False, ***kwargs*)

An asynchronous version of **MagicMock**. The **AsyncMock** object will behave so the object is recognized as an async function, and the result of a call is an awaitable.

```
>>> mock = AsyncMock()
>>> asyncio.iscoroutinefunction(mock)
True
>>> inspect.isawaitable(mock())
True
```

The result of `mock()` is an async function which will have the outcome of `side_effect` or `return_value` after it has been awaited:

- if `side_effect` is a function, the async function will return the result of that function,
- if `side_effect` is an exception, the async function will raise the exception,
- if `side_effect` is an iterable, the async function will return the next value of the iterable, however, if the sequence of result is exhausted, `StopAsyncIteration` is raised immediately,
- if `side_effect` is not defined, the async function will return the value defined by `return_value`, hence, by default, the async function returns a new **AsyncMock** object.

Setting the *spec* of a **Mock** or **MagicMock** to an async function will result in a coroutine object being returned after calling.

```
>>> async def async_func(): pass
...
>>> mock = MagicMock(async_func)
>>> mock
<MagicMock spec='function' id='...'>
>>> mock()
<coroutine object AsyncMockMixin._mock_call at ...>
```

Setting the *spec* of a **Mock**, **MagicMock**, or **AsyncMock** to a class with asynchronous and synchronous functions will automatically detect the synchronous functions and set them as **MagicMock** (if the parent mock is **AsyncMock** or **MagicMock**) or **Mock** (if the parent mock is **Mock**). All asynchronous functions will be **AsyncMock**.

```
>>> class ExampleClass:
...     def sync_foo():
...         pass
...     async def async_foo():
...         pass
...
>>> a_mock = AsyncMock(ExampleClass)
>>> a_mock.sync_foo
<MagicMock name='mock.sync_foo' id='...'>
>>> a_mock.async_foo
<AsyncMock name='mock.async_foo' id='...'>
>>> mock = Mock(ExampleClass)
>>> mock.sync_foo
<Mock name='mock.sync_foo' id='...'>
>>> mock.async_foo
<AsyncMock name='mock.async_foo' id='...'>
```

New in version 3.8.

assert_awaited()

Assert that the mock was awaited at least once. Note that this is separate from the object having been called, the `await` keyword must be used:

```
>>> mock = AsyncMock()
>>> async def main(coroutine_mock):
...     await coroutine_mock
...
>>> coroutine_mock = mock()
>>> mock.called
True
>>> mock.assert_awaited()
```

```
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awai
>>> asyncio.run(main(coroutine_mock))
>>> mock.assert_awaited()
```

assert_awaited_once()

Assert that the mock was awaited exactly once.

```
>>> mock = AsyncMock()
>>> async def main():
...     await mock()
...
>>> asyncio.run(main())
>>> mock.assert_awaited_once()
>>> asyncio.run(main())
>>> mock.method.assert_awaited_once()
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awai
```

assert_awaited_with(**args*, ***kwargs*)

Assert that the last await was with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_with('foo', bar='bar')
>>> mock.assert_awaited_with('other')
Traceback (most recent call last):
...
AssertionError: expected call not found.
Expected: mock('other')
Actual: mock('foo', bar='bar')
```

assert_awaited_once_with(**args*, ***kwargs*)

Assert that the mock was awaited exactly once and with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='b
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='b
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awai
```

assert_any_await(**args*, ***kwargs*)

Assert the mock has ever been awaited with the specified arguments.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> asyncio.run(main('hello'))
>>> mock.assert_any_await('foo', bar='bar')
>>> mock.assert_any_await('other')
Traceback (most recent call last):
...
AssertionError: mock('other') await not found
```

assert_has_awaits(*calls*, *any_order*=*False*)

Assert the mock has been awaited with the specified calls. The **`await_args_list`** list is checked for the awaits.

If *any_order* is false then the awaits must be sequential.

There can be extra calls before or after the specified awaits.

If *any_order* is true then the awaits can be in any order, but they must all appear in **await_args_list**.

```
>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> calls = [call("foo"), call("bar")]
>>> mock.assert_has_awaits(calls)
Traceback (most recent call last):
...
AssertionError: Awaits not found.
Expected: [call('foo'), call('bar')]
Actual: []
>>> asyncio.run(main('foo'))
>>> asyncio.run(main('bar'))
>>> mock.assert_has_awaits(calls)
```

assert_not_awaited()

Assert that the mock was never awaited.

```
>>> mock = AsyncMock()
>>> mock.assert_not_awaited()
```

reset_mock(**args*, ***kwargs*)

See **Mock.reset_mock()**. Also sets **await_count** to 0, **await_args** to None, and clears the **await_args_list**.

await_count

An integer keeping track of how many times the mock object has been awaited.

```
>>> mock = AsyncMock()
>>> async def main():
```

```
...     await mock()
...
>>> asyncio.run(main())
>>> mock.await_count
1
>>> asyncio.run(main())
>>> mock.await_count
2
```

await_args

This is either `None` (if the mock hasn't been awaited), or the arguments that the mock was last awaited with. Functions the same as **`Mock.call_args`**.

```
>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...
>>> mock.await_args
>>> asyncio.run(main('foo'))
>>> mock.await_args
call('foo')
>>> asyncio.run(main('bar'))
>>> mock.await_args
call('bar')
```

await_args_list

This is a list of all the awaits made to the mock object in sequence (so the length of the list is the number of times it has been awaited). Before any awaits have been made it is an empty list.

```
>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...
>>> mock.await_args_list
[]
```

```
>>> asyncio.run(main('foo'))
>>> mock.await_args_list
[call('foo')]
>>> asyncio.run(main('bar'))
>>> mock.await_args_list
[call('foo'), call('bar')]
```

Calling

Mock objects are callable. The call will return the value set as the **`return_value`** attribute. The default return value is a new Mock object; it is created the first time the return value is accessed (either explicitly or by calling the Mock) - but it is stored and the same one returned each time.

Calls made to the object will be recorded in the attributes like **`call_args`** and **`call_args_list`**.

If **`side_effect`** is set then it will be called after the call has been recorded, so if **`side_effect`** raises an exception the call is still recorded.

The simplest way to make a mock raise an exception when called is to make **`side_effect`** an exception class or instance:

```
>>> m = MagicMock(side_effect=IndexError)
>>> m(1, 2, 3)
Traceback (most recent call last):
  ...
IndexError
>>> m.mock_calls
[call(1, 2, 3)]
>>> m.side_effect = KeyError('Bang!')
>>> m('two', 'three', 'four')
Traceback (most recent call last):
  ...
KeyError: 'Bang!'
>>> m.mock_calls
[call(1, 2, 3), call('two', 'three', 'four')]
```

If **side_effect** is a function then whatever that function returns is what calls to the mock return. The **side_effect** function is called with the same arguments as the mock. This allows you to vary the return value of the call dynamically, based on the input:

```
>>> def side_effect(value):
...     return value + 1
...
>>> m = MagicMock(side_effect=side_effect)
>>> m(1)
2
>>> m(2)
3
>>> m.mock_calls
[call(1), call(2)]
```

If you want the mock to still return the default return value (a new mock), or any set return value, then there are two ways of doing this. Either return **mock.return_value** from inside **side_effect**, or return **DEFAULT**:

```
>>> m = MagicMock()
>>> def side_effect(*args, **kwargs):
...     return m.return_value
...
>>> m.side_effect = side_effect
>>> m.return_value = 3
>>> m()
3
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> m.side_effect = side_effect
>>> m()
3
```

To remove a **side_effect**, and return to the default behaviour, set the **side_effect** to `None`:

```
>>> m = MagicMock(return_value=6)
```

```
>>> def side_effect(*args, **kwargs):
...     return 3
...
>>> m.side_effect = side_effect
>>> m()
3
>>> m.side_effect = None
>>> m()
6
```

The **`side_effect`** can also be any iterable object. Repeated calls to the mock will return values from the iterable (until the iterable is exhausted and a **`StopIteration`** is raised):

```
>>> m = MagicMock(side_effect=[1, 2, 3])
>>> m()
1
>>> m()
2
>>> m()
3
>>> m()
Traceback (most recent call last):
  ...
StopIteration
```

If any members of the iterable are exceptions they will be raised instead of returned:

```
>>> iterable = (33, ValueError, 66)
>>> m = MagicMock(side_effect=iterable)
>>> m()
33
>>> m()
Traceback (most recent call last):
 ...
ValueError
>>> m()
66
```

Deleting Attributes

Mock objects create attributes on demand. This allows them to pretend to be objects of any type.

You may want a mock object to return `False` to a **`hasattr()`** call, or raise an **`AttributeError`** when an attribute is fetched. You can do this by providing an object as a **`spec`** for a mock, but that isn't always convenient.

You "block" attributes by deleting them. Once deleted, accessing an attribute will raise an **`AttributeError`**.

```
>>> mock = MagicMock()
>>> hasattr(mock, 'm')
True
>>> del mock.m
>>> hasattr(mock, 'm')
False
>>> del mock.f
>>> mock.f
Traceback (most recent call last):
    ...
AttributeError: f
```

Mock names and the name attribute

Since "name" is an argument to the **`Mock`** constructor, if you want your mock object to have a "name" attribute you can't just pass it in at creation time. There are two alternatives. One option is to use **`configure_mock()`**:

```
>>> mock = MagicMock()
>>> mock.configure_mock(name='my_name')
>>> mock.name
'my_name'
```

A simpler option is to simply set the "name" attribute after mock creation:

```
>>> mock = MagicMock()
>>> mock.name = "foo"
```

Attaching Mocks as Attributes

When you attach a mock as an attribute of another mock (or as the return value) it becomes a "child" of that mock. Calls to the child are recorded in the **`method_calls`** and **`mock_calls`** attributes of the parent. This is useful for configuring child mocks and then attaching them to the parent, or for attaching mocks to a parent that records all calls to the children and allows you to make assertions about the order of calls between mocks:

```
>>> parent = MagicMock()
>>> child1 = MagicMock(return_value=None)
>>> child2 = MagicMock(return_value=None)
>>> parent.child1 = child1
>>> parent.child2 = child2
>>> child1(1)
>>> child2(2)
>>> parent.mock_calls
[call.child1(1), call.child2(2)]
```

The exception to this is if the mock has a name. This allows you to prevent the "parenting" if for some reason you don't want it to happen.

```
>>> mock = MagicMock()
>>> not_a_child = MagicMock(name='not-a-child')
>>> mock.attribute = not_a_child
>>> mock.attribute()
<MagicMock name='not-a-child()' id='...'>
>>> mock.mock_calls
[]
```

Mocks created for you by **`patch()`** are automatically given names. To attach mocks that have names to a parent you use the **`attach_mock()`** method:

```
>>> thing1 = object()
```

```
>>> thing2 = object()
>>> parent = MagicMock()
>>> with patch('__main__.thing1', return_value=None) as
...     with patch('__main__.thing2', return_value=None)
...         parent.attach_mock(child1, 'child1')
...         parent.attach_mock(child2, 'child2')
...         child1('one')
...         child2('two')
...
>>> parent.mock_calls
[call.child1('one'), call.child2('two')]
```

1

The only exceptions are magic methods and attributes (those that have leading and trailing double underscores). Mock doesn't create these but instead raises an **AttributeError**. This is because the interpreter will often implicitly request these methods, and gets *very* confused to get a new Mock object when it expects a magic method. If you need magic method support see magic methods.

The patchers

The patch decorators are used for patching objects only within the scope of the function they decorate. They automatically handle the unpatching for you, even if exceptions are raised. All of these functions can also be used in with statements or as class decorators.

patch

Note

The key is to do the patching in the right namespace. See the section where to patch.

unittest.mock.patch(*target*, *new=DEFAULT*, *spec=None*, *create=False*, *spec_set=None*, *autospec=None*, *new_callable=None*, ***kwargs*)

patch() acts as a function decorator, class decorator or a context manager. Inside the body of the function or with statement, the *target* is patched with a *new* object. When the function/with statement exits the patch is undone.

If *new* is omitted, then the target is replaced with an **AsyncMock** if the patched object is an async function or a **MagicMock** otherwise. If **patch()** is used as a decorator and *new* is omitted, the created mock is passed in as an extra argument to the decorated function. If **patch()** is used as a context manager the created mock is returned by the context manager.

target should be a string in the form `'package.module.ClassName'`. The *target* is imported and the specified object replaced with the *new* object, so the *target* must be importable from the environment you are calling **patch()** from. The target is imported when the decorated function is executed, not at decoration time.

The *spec* and *spec_set* keyword arguments are passed to the **MagicMock** if patch is creating one for you.

In addition you can pass `spec=True` or `spec_set=True`, which causes patch to pass in the object being mocked as the spec/spec_set object.

new_callable allows you to specify a different class, or callable object, that will be called to create the *new* object. By default **AsyncMock** is used for async functions and **MagicMock** for the rest.

A more powerful form of *spec* is *autospec*. If you set `autospec=True` then the mock will be created with a spec from the object being replaced. All attributes of the mock will also have the spec of the corresponding attribute of the object being replaced. Methods and functions being mocked will have their arguments checked and will raise a **TypeError** if they are called with the wrong signature. For mocks replacing a class, their return value (the 'instance') will have the same spec as the class. See the **create_autospec()** function

and Autospeccing.

Instead of `autospec=True` you can pass `autospec=some_object` to use an arbitrary object as the spec instead of the one being replaced.

By default **`patch()`** will fail to replace attributes that don't exist. If you pass in `create=True`, and the attribute doesn't exist, patch will create the attribute for you when the patched function is called, and delete it again after the patched function has exited. This is useful for writing tests against attributes that your production code creates at runtime. It is off by default because it can be dangerous. With it switched on you can write passing tests against APIs that don't actually exist!

Note

Changed in version 3.5: If you are patching builtins in a module then you don't need to pass `create=True`, it will be added by default.

Patch can be used as a **`TestCase`** class decorator. It works by decorating each test method in the class. This reduces the boilerplate code when your test methods share a common patchings set. **`patch()`** finds tests by looking for method names that start with `patch.TEST_PREFIX`. By default this is `'test'`, which matches the way **`unittest`** finds tests. You can specify an alternative prefix by setting `patch.TEST_PREFIX`.

Patch can be used as a context manager, with the with statement. Here the patching applies to the indented block after the with statement. If you use "as" then the patched object will be bound to the name after the "as"; very useful if **`patch()`** is creating a mock object for you.

`patch()` takes arbitrary keyword arguments. These will be passed to **`AsyncMock`** if the patched object is asynchronous, to **`MagicMock`** otherwise or to *new_callable* if specified.

`patch.dict(...)`, `patch.multiple(...)` and `patch.object(...)` are available for alternate use-cases.

`patch()` as function decorator, creating the mock for you and passing it into the decorated function:

```
>>> @patch('__main__.SomeClass')
... def function(normal_argument, mock_class):
...     print(mock_class is SomeClass)
...
>>> function(None)
True
```

Patching a class replaces the class with a **`MagicMock`** *instance*. If the class is instantiated in the code under test then it will be the **`return_value`** of the mock that will be used.

If the class is instantiated multiple times you could use **`side_effect`** to return a new mock each time. Alternatively you can set the *return_value* to be anything you want.

To configure return values on methods of *instances* on the patched class you must do this on the **`return_value`**. For example:

```
>>> class Class:
...     def method(self):
...         pass
...
>>> with patch('__main__.Class') as MockClass:
...     instance = MockClass.return_value
...     instance.method.return_value = 'foo'
...     assert Class() is instance
...     assert Class().method() == 'foo'
...
```

If you use *spec* or *spec_set* and **`patch()`** is replacing a *class*, then the return value of the created mock will have the same spec.

```
>>> Original = Class
>>> patcher = patch('__main__.Class', spec=True)
```

```
>>> MockClass = patcher.start()
>>> instance = MockClass()
>>> assert isinstance(instance, Original)
>>> patcher.stop()
```

The *new_callable* argument is useful where you want to use an alternative class to the default **MagicMock** for the created mock. For example, if you wanted a **NonCallableMock** to be used:

```
>>> thing = object()
>>> with patch('__main__.thing', new_callable=NonCallabl
...     assert thing is mock_thing
...     thing()
...
Traceback (most recent call last):
  ...
TypeError: 'NonCallableMock' object is not callable
```

Another use case might be to replace an object with an **io.StringIO** instance:

```
>>> from io import StringIO
>>> def foo():
...     print('Something')
...
>>> @patch('sys.stdout', new_callable=StringIO)
... def test(mock_stdout):
...     foo()
...     assert mock_stdout.getvalue() == 'Something\n'
...
>>> test()
```

When **patch()** is creating a mock for you, it is common that the first thing you need to do is to configure the mock. Some of that configuration can be done in the call to patch. Any arbitrary keywords you pass into the call will be used to set attributes on the created mock:

```
>>> patcher = patch('__main__.thing', first='one', secon
>>> mock_thing = patcher.start()
```

```
>>> mock_thing.first
'one'
>>> mock_thing.second
'two'
```

As well as attributes on the created mock attributes, like the **`return_value`** and **`side_effect`**, of child mocks can also be configured. These aren't syntactically valid to pass in directly as keyword arguments, but a dictionary with these as keys can still be expanded into a **`patch()`** call using `**`:

```
>>> config = {'method.return_value': 3, 'other.side_effe
>>> patcher = patch('__main__.thing', **config)
>>> mock_thing = patcher.start()
>>> mock_thing.method()
3
>>> mock_thing.other()
Traceback (most recent call last):
  ...
KeyError
```

By default, attempting to patch a function in a module (or a method or an attribute in a class) that does not exist will fail with **`AttributeError`**:

```
>>> @patch('sys.non_existing_attribute', 42)
... def test():
...     assert sys.non_existing_attribute == 42
...
>>> test()
Traceback (most recent call last):
  ...
AttributeError: <module 'sys' (built-in)> does not have
```

but adding `create=True` in the call to **`patch()`** will make the previous example work as expected:

```
>>> @patch('sys.non_existing_attribute', 42, create=True
... def test(mock_stdout):
...     assert sys.non_existing_attribute == 42
```

```
...
>>> test()
```

Changed in version 3.8: **patch()** now returns an **AsyncMock** if the target is an async function.

patch.object

patch.object(*target*, *attribute*, *new=DEFAULT*, *spec=None*, *create=False*, *spec_set=None*, *autospec=None*, *new_callable=None*, ***kwargs*)

patch the named member (*attribute*) on an object (*target*) with a mock object.

patch.object() can be used as a decorator, class decorator or a context manager. Arguments *new*, *spec*, *create*, *spec_set*, *autospec* and *new_callable* have the same meaning as for **patch()**. Like **patch()**, **patch.object()** takes arbitrary keyword arguments for configuring the mock object it creates.

When used as a class decorator **patch.object()** honours `patch.TEST_PREFIX` for choosing which methods to wrap.

You can either call **patch.object()** with three arguments or two arguments. The three argument form takes the object to be patched, the attribute name and the object to replace the attribute with.

When calling with the two argument form you omit the replacement object, and a mock is created for you and passed in as an extra argument to the decorated function:

```
>>> @patch.object(SomeClass, 'class_method')
... def test(mock_method):
...     SomeClass.class_method(3)
...     mock_method.assert_called_with(3)
...
>>> test()
```

spec, *create* and the other arguments to **patch.object()** have the

same meaning as they do for `patch()`.

patch.dict

patch.dict(*in_dict*, *values*=*()*, *clear*=*False*, ***kwargs*)

Patch a dictionary, or dictionary like object, and restore the dictionary to its original state after the test.

in_dict can be a dictionary or a mapping like container. If it is a mapping then it must at least support getting, setting and deleting items plus iterating over keys.

in_dict can also be a string specifying the name of the dictionary, which will then be fetched by importing it.

values can be a dictionary of values to set in the dictionary. *values* can also be an iterable of `(key, value)` pairs.

If *clear* is true then the dictionary will be cleared before the new values are set.

`patch.dict()` can also be called with arbitrary keyword arguments to set values in the dictionary.

Changed in version 3.8: `patch.dict()` now returns the patched dictionary when used as a context manager.

`patch.dict()` can be used as a context manager, decorator or class decorator:

```
>>> foo = {}
>>> @patch.dict(foo, {'newkey': 'newvalue'})
... def test():
...     assert foo == {'newkey': 'newvalue'}
>>> test()
>>> assert foo == {}
```

When used as a class decorator `patch.dict()` honours `patch.TEST_PREFIX` (default to `'test'`) for choosing which methods to wrap:

```
>>> import os
>>> import unittest
>>> from unittest.mock import patch
>>> @patch.dict('os.environ', {'newkey': 'newvalue'})
... class TestSample(unittest.TestCase):
...     def test_sample(self):
...         self.assertEqual(os.environ['newkey'], 'newv
```

If you want to use a different prefix for your test, you can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`. For more details about how to change the value of see TEST_PREFIX.

`patch.dict()` can be used to add members to a dictionary, or simply let a test change a dictionary, and ensure the dictionary is restored when the test ends.

```
>>> foo = {}
>>> with patch.dict(foo, {'newkey': 'newvalue'}) as patc
...     assert foo == {'newkey': 'newvalue'}
...     assert patched_foo == {'newkey': 'newvalue'}
...     # You can add, update or delete keys of foo (or
...     patched_foo['spam'] = 'eggs'
...
>>> assert foo == {}
>>> assert patched_foo == {}

>>> import os
>>> with patch.dict('os.environ', {'newkey': 'newvalue'}
...     print(os.environ['newkey'])
...
newvalue
>>> assert 'newkey' not in os.environ
```

Keywords can be used in the **`patch.dict()`** call to set values in the dictionary:

```
>>> mymodule = MagicMock()
>>> mymodule.function.return_value = 'fish'
>>> with patch.dict('sys.modules', mymodule=mymodule):
```

```
...     import mymodule
...     mymodule.function('some', 'args')
...
'fish'
```

patch.dict() can be used with dictionary like objects that aren't actually dictionaries. At the very minimum they must support item getting, setting, deleting and either iteration or membership test. This corresponds to the magic methods **__getitem__()**, **__setitem__()**, **__delitem__()** and either **__iter__()** or **__contains__()**.

```
>>> class Container:
...     def __init__(self):
...         self.values = {}
...     def __getitem__(self, name):
...         return self.values[name]
...     def __setitem__(self, name, value):
...         self.values[name] = value
...     def __delitem__(self, name):
...         del self.values[name]
...     def __iter__(self):
...         return iter(self.values)
...
>>> thing = Container()
>>> thing['one'] = 1
>>> with patch.dict(thing, one=2, two=3):
...     assert thing['one'] == 2
...     assert thing['two'] == 3
...
>>> assert thing['one'] == 1
>>> assert list(thing) == ['one']
```

patch.multiple

patch.multiple(*target*, *spec*=*None*, *create*=*False*, *spec_set*=*None*, *autospec*=*None*, *new_callable*=*None*, ***kwargs*)

Perform multiple patches in a single call. It takes the object to be patched (either as an object or a string to fetch the object

by importing) and keyword arguments for the patches:

```
with patch.multiple(settings, FIRST_PATCH='one', SE
    ...
```

Use **DEFAULT** as the value if you want **patch.multiple()** to create mocks for you. In this case the created mocks are passed into a decorated function by keyword, and a dictionary is returned when **patch.multiple()** is used as a context manager.

patch.multiple() can be used as a decorator, class decorator or a context manager. The arguments *spec*, *spec_set*, *create*, *autospec* and *new_callable* have the same meaning as for **patch()**. These arguments will be applied to *all* patches done by **patch.multiple()**.

When used as a class decorator **patch.multiple()** honours `patch.TEST_PREFIX` for choosing which methods to wrap.

If you want **patch.multiple()** to create mocks for you, then you can use **DEFAULT** as the value. If you use **patch.multiple()** as a decorator then the created mocks are passed into the decorated function by keyword.

```
>>> thing = object()
>>> other = object()

>>> @patch.multiple('__main__', thing=DEFAULT, other=DEF
... def test_function(thing, other):
...     assert isinstance(thing, MagicMock)
...     assert isinstance(other, MagicMock)
...
>>> test_function()
```

patch.multiple() can be nested with other `patch` decorators, but put arguments passed by keyword *after* any of the standard arguments created by **patch()**:

```
>>> @patch('sys.exit')
... @patch.multiple('__main__', thing=DEFAULT, other=DEF
... def test_function(mock_exit, other, thing):
...     assert 'other' in repr(other)
...     assert 'thing' in repr(thing)
...     assert 'exit' in repr(mock_exit)
...
>>> test_function()
```

If **patch.multiple()** is used as a context manager, the value returned by the context manager is a dictionary where created mocks are keyed by name:

```
>>> with patch.multiple('__main__', thing=DEFAULT, other
...     assert 'other' in repr(values['other'])
...     assert 'thing' in repr(values['thing'])
...     assert values['thing'] is thing
...     assert values['other'] is other
...
```

patch methods: start and stop

All the patchers have **start()** and **stop()** methods. These make it simpler to do patching in `setUp` methods or where you want to do multiple patches without nesting decorators or with statements.

To use them call **patch()**, **patch.object()** or **patch.dict()** as normal and keep a reference to the returned `patcher` object. You can then call **start()** to put the patch in place and **stop()** to undo it.

If you are using **patch()** to create a mock for you then it will be returned by the call to `patcher.start`.

```
>>> patcher = patch('package.module.ClassName')
>>> from package import module
>>> original = module.ClassName
>>> new_mock = patcher.start()
>>> assert module.ClassName is not original
>>> assert module.ClassName is new_mock
```

```
>>> patcher.stop()
>>> assert module.ClassName is original
>>> assert module.ClassName is not new_mock
```

A typical use case for this might be for doing multiple patches in the `setUp` method of a **`TestCase`**:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         self.patcher1 = patch('package.module.Class1
...         self.patcher2 = patch('package.module.Class2
...         self.MockClass1 = self.patcher1.start()
...         self.MockClass2 = self.patcher2.start()
...
...     def tearDown(self):
...         self.patcher1.stop()
...         self.patcher2.stop()
...
...     def test_something(self):
...         assert package.module.Class1 is self.MockCla
...         assert package.module.Class2 is self.MockCla
...
>>> MyTest('test_something').run()
```

Caution

If you use this technique you must ensure that the patching is "undone" by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the `setUp` then `tearDown` is not called.
`unittest.TestCase.addCleanup()` makes this easier:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('package.module.Class')
...         self.MockClass = patcher.start()
...         self.addCleanup(patcher.stop)
...
...     def test_something(self):
```

```
...         assert package.module.Class is self.MockCla
...
```

As an added bonus you no longer need to keep a reference to the `patcher` object.

It is also possible to stop all patches which have been started by using **`patch.stopall()`**.

patch.stopall()

Stop all active patches. Only stops patches started with `start`.

patch builtins

You can patch any builtins within a module. The following example patches builtin **`ord()`**:

```
>>> @patch('__main__.ord')
... def test(mock_ord):
...     mock_ord.return_value = 101
...     print(ord('c'))
...
>>> test()
101
```

TEST_PREFIX

All of the patchers can be used as class decorators. When used in this way they wrap every test method on the class. The patchers recognise methods that start with `'test'` as being test methods. This is the same way that the **`unittest.TestLoader`** finds test methods by default.

It is possible that you want to use a different prefix for your tests. You can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`:

```
>>> patch.TEST_PREFIX = 'foo'
```

```
>>> value = 3
>>>
>>> @patch('__main__.value', 'not three')
... class Thing:
...     def foo_one(self):
...         print(value)
...     def foo_two(self):
...         print(value)
...
>>>
>>> Thing().foo_one()
not three
>>> Thing().foo_two()
not three
>>> value
3
```

Nesting Patch Decorators

If you want to perform multiple patches then you can simply stack up the decorators.

You can stack up multiple patch decorators using this pattern:

```
>>> @patch.object(SomeClass, 'class_method')
... @patch.object(SomeClass, 'static_method')
... def test(mock1, mock2):
...     assert SomeClass.static_method is mock1
...     assert SomeClass.class_method is mock2
...     SomeClass.static_method('foo')
...     SomeClass.class_method('bar')
...     return mock1, mock2
...
>>> mock1, mock2 = test()
>>> mock1.assert_called_once_with('foo')
>>> mock2.assert_called_once_with('bar')
```

Note that the decorators are applied from the bottom upwards. This is the standard way that Python applies decorators. The order of the

created mocks passed into your test function matches this order.

Where to patch

`patch()` works by (temporarily) changing the object that a *name* points to with another one. There can be many names pointing to any individual object, so for patching to work you must ensure that you patch the name used by the system under test.

The basic principle is that you patch where an object is *looked up*, which is not necessarily the same place as where it is defined. A couple of examples will help to clarify this.

Imagine we have a project that we want to test with the following structure:

```
a.py
    -> Defines SomeClass

b.py
    -> from a import SomeClass
    -> some_function instantiates SomeClass
```

Now we want to test `some_function` but we want to mock out `SomeClass` using **`patch()`**. The problem is that when we import module b, which we will have to do then it imports `SomeClass` from module a. If we use **`patch()`** to mock out `a.SomeClass` then it will have no effect on our test; module b already has a reference to the *real* `SomeClass` and it looks like our patching had no effect.

The key is to patch out `SomeClass` where it is used (or where it is looked up). In this case `some_function` will actually look up `SomeClass` in module b, where we have imported it. The patching should look like:

```
@patch('b.SomeClass')
```

However, consider the alternative scenario where instead of `from a import SomeClass` module b does `import a` and `some_function` uses `a.SomeClass`. Both of these import forms

are common. In this case the class we want to patch is being looked up in the module and so we have to patch `a.SomeClass` instead:

```
@patch('a.SomeClass')
```

Patching Descriptors and Proxy Objects

Both patch and patch.object correctly patch and restore descriptors: class methods, static methods and properties. You should patch these on the *class* rather than an instance. They also work with *some* objects that proxy attribute access, like the django settings object [https://web.archive.org/web/20200603181648/http://www.voidspace.org.uk/python/weblog/arch_d7_2010_12_04.shtml#e1198].

MagicMock and magic method support

Mocking Magic Methods

`Mock` supports mocking the Python protocol methods, also known as "magic methods". This allows mock objects to replace containers or other objects that implement Python protocols.

Because magic methods are looked up differently from normal methods 2, this support has been specially implemented. This means that only specific magic methods are supported. The supported list includes *almost* all of them. If there are any missing that you need please let us know.

You mock magic methods by setting the method you are interested in to a function or a mock instance. If you are using a function then it *must* take `self` as the first argument 3.

```
>>> def __str__(self):
...     return 'fooble'
...
>>> mock = Mock()
>>> mock.__str__ = __str__
>>> str(mock)
'fooble'
```

```
>>> mock = Mock()
>>> mock.__str__ = Mock()
>>> mock.__str__.return_value = 'fooble'
>>> str(mock)
'fooble'

>>> mock = Mock()
>>> mock.__iter__ = Mock(return_value=iter([]))
>>> list(mock)
[]
```

One use case for this is for mocking objects used as context managers in a **with** statement:

```
>>> mock = Mock()
>>> mock.__enter__ = Mock(return_value='foo')
>>> mock.__exit__ = Mock(return_value=False)
>>> with mock as m:
...     assert m == 'foo'
...
>>> mock.__enter__.assert_called_with()
>>> mock.__exit__.assert_called_with(None, None, None)
```

Calls to magic methods do not appear in **method_calls**, but they are recorded in **mock_calls**.

Note

If you use the *spec* keyword argument to create a mock then attempting to set a magic method that isn't in the spec will raise an **AttributeError**.

The full list of supported magic methods is:

- `__hash__`, `__sizeof__`, `__repr__` and `__str__`
- `__dir__`, `__format__` and `__subclasses__`
- `__round__`, `__floor__`, `__trunc__` and `__ceil__`
- Comparisons: `__lt__`, `__gt__`, `__le__`, `__ge__`, `__eq__` and `__ne__`
- Container methods: `__getitem__`, `__setitem__`,

`__delitem__`, `__contains__`, `__len__`, `__iter__`, `__reversed__` and `__missing__`

- Context manager: `__enter__`, `__exit__`, `__aenter__` and `__aexit__`
- Unary numeric methods: `__neg__`, `__pos__` and `__invert__`
- The numeric methods (including right hand and in-place variants): `__add__`, `__sub__`, `__mul__`, `__matmul__`, `__truediv__`, `__floordiv__`, `__mod__`, `__divmod__`, `__lshift__`, `__rshift__`, `__and__`, `__xor__`, `__or__`, and `__pow__`
- Numeric conversion methods: `__complex__`, `__int__`, `__float__` and `__index__`
- Descriptor methods: `__get__`, `__set__` and `__delete__`
- Pickling: `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
- File system path representation: `__fspath__`
- Asynchronous iteration methods: `__aiter__` and `__anext__`

Changed in version 3.8: Added support for **`os.PathLike.__fspath__()`**.

Changed in version 3.8: Added support for `__aenter__`, `__aexit__`, `__aiter__` and `__anext__`.

The following methods exist but are *not* supported as they are either in use by mock, can't be set dynamically, or can cause problems:

- `__getattr__`, `__setattr__`, `__init__` and `__new__`
- `__prepare__`, `__instancecheck__`, `__subclasscheck__`, `__del__`

Magic Mock

There are two `MagicMock` variants: **`MagicMock`** and **`NonCallableMagicMock`**.

class unittest.mock.MagicMock(**args*, ***kw*)

`MagicMock` is a subclass of **`Mock`** with default implementations of most of the magic methods. You can use `MagicMock` without having to configure the magic methods yourself.

The constructor parameters have the same meaning as for **`Mock`**.

If you use the *spec* or *spec_set* arguments then *only* magic methods that exist in the spec will be created.

class unittest.mock.NonCallableMagicMock(**args*, ***kw*)

A non-callable version of **`MagicMock`**.

The constructor parameters have the same meaning as for **`MagicMock`**, with the exception of *return_value* and *side_effect* which have no meaning on a non-callable mock.

The magic methods are setup with **`MagicMock`** objects, so you can configure them and use them in the usual way:

```
>>> mock = MagicMock()
>>> mock[3] = 'fish'
>>> mock.__setitem__.assert_called_with(3, 'fish')
>>> mock.__getitem__.return_value = 'result'
>>> mock[2]
'result'
```

By default many of the protocol methods are required to return objects of a specific type. These methods are preconfigured with a default return value, so that they can be used without you having to do anything if you aren't interested in the return value. You can still *set* the return value manually if you want to change the default.

Methods and their defaults:

- `__lt__`: `NotImplemented`
- `__gt__`: `NotImplemented`
- `__le__`: `NotImplemented`
- `__ge__`: `NotImplemented`

- `__int__`: `1`
- `__contains__`: `False`
- `__len__`: `0`
- `__iter__`: `iter([])`
- `__exit__`: `False`
- `__aexit__`: `False`
- `__complex__`: `1j`
- `__float__`: `1.0`
- `__bool__`: `True`
- `__index__`: `1`
- `__hash__`: default hash for the mock
- `__str__`: default str for the mock
- `__sizeof__`: default sizeof for the mock

For example:

```
>>> mock = MagicMock()
>>> int(mock)
1
>>> len(mock)
0
>>> list(mock)
[]
>>> object() in mock
False
```

The two equality methods, **`__eq__()`** and **`__ne__()`**, are special. They do the default equality comparison on identity, using the **`side_effect`** attribute, unless you change their return value to return something else:

```
>>> MagicMock() == 3
False
>>> MagicMock() != 3
True
>>> mock = MagicMock()
>>> mock.__eq__.return_value = True
>>> mock == 3
True
```

The return value of **`MagicMock.__iter__()`** can be any iterable object and isn't required to be an iterator:

```
>>> mock = MagicMock()
>>> mock.__iter__.return_value = ['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
```

If the return value *is* an iterator, then iterating over it once will consume it and subsequent iterations will result in an empty list:

```
>>> mock.__iter__.return_value = iter(['a', 'b', 'c'])
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
[]
```

`MagicMock` has all of the supported magic methods configured except for some of the obscure and obsolete ones. You can still set these up if you want.

Magic methods that are supported but not setup by default in `MagicMock` are:

- `__subclasses__`
- `__dir__`
- `__format__`
- `__get__`, `__set__` and `__delete__`
- `__reversed__` and `__missing__`
- `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
- `__getformat__`

2

Magic methods *should* be looked up on the class rather than the instance. Different versions of Python are inconsistent about applying this rule. The supported protocol methods should work with all supported versions of Python.

[3]

The function is basically hooked up to the class, but each `Mock` instance is kept isolated from the others.

Helpers

sentinel

unittest.mock.sentinel

The `sentinel` object provides a convenient way of providing unique objects for your tests.

Attributes are created on demand when you access them by name. Accessing the same attribute will always return the same object. The objects returned have a sensible repr so that test failure messages are readable.

Changed in version 3.7: The `sentinel` attributes now preserve their identity when they are **`copied`** or **`pickled`**.

Sometimes when testing you need to test that a specific object is passed as an argument to another method, or returned. It can be common to create named sentinel objects to test this. **`sentinel`** provides a convenient way of creating and testing the identity of objects like this.

In this example we monkey patch `method` to return `sentinel.some_object`:

```
>>> real = ProductionClass()
>>> real.method = Mock(name="method")
>>> real.method.return_value = sentinel.some_object
>>> result = real.method()
>>> assert result is sentinel.some_object
>>> result
sentinel.some_object
```

DEFAULT

unittest.mock.DEFAULT

The **DEFAULT** object is a pre-created sentinel (actually `sentinel.DEFAULT`). It can be used by **side_effect** functions to indicate that the normal return value should be used.

call

unittest.mock.call(**args*, ***kwargs*)

call() is a helper object for making simpler assertions, for comparing with **call_args**, **call_args_list**, **mock_calls** and **method_calls**. **call()** can also be used with **assert_has_calls()**.

```
>>> m = MagicMock(return_value=None)
>>> m(1, 2, a='foo', b='bar')
>>> m()
>>> m.call_args_list == [call(1, 2, a='foo', b='bar
True
```

call.call_list()

For a call object that represents multiple calls, **call_list()** returns a list of all the intermediate calls as well as the final call.

`call_list` is particularly useful for making assertions on "chained calls". A chained call is multiple calls on a single line of code. This results in multiple entries in **mock_calls** on a mock. Manually constructing the sequence of calls can be tedious.

call_list() can construct the sequence of calls from the same chained call:

```
>>> m = MagicMock()
>>> m(1).method(arg='foo').other('bar')(2.0)
<MagicMock name='mock().method().other()()' id='...'>
>>> kall = call(1).method(arg='foo').other('bar')(2.0)
>>> kall.call_list()
```

```
[call(1),
 call().method(arg='foo'),
 call().method().other('bar'),
 call().method().other()(2.0)]
>>> m.mock_calls == kall.call_list()
True
```

A `call` object is either a tuple of (positional args, keyword args) or (name, positional args, keyword args) depending on how it was constructed. When you construct them yourself this isn't particularly interesting, but the `call` objects that are in the **`Mock.call_args`**, **`Mock.call_args_list`** and **`Mock.mock_calls`** attributes can be introspected to get at the individual arguments they contain.

The `call` objects in **`Mock.call_args`** and **`Mock.call_args_list`** are two-tuples of (positional args, keyword args) whereas the `call` objects in **`Mock.mock_calls`**, along with ones you construct yourself, are three-tuples of (name, positional args, keyword args).

You can use their "tupleness" to pull out the individual arguments for more complex introspection and assertions. The positional arguments are a tuple (an empty tuple if there are no positional arguments) and the keyword arguments are a dictionary:

```
>>> m = MagicMock(return_value=None)
>>> m(1, 2, 3, arg='one', arg2='two')
>>> kall = m.call_args
>>> kall.args
(1, 2, 3)
>>> kall.kwargs
{'arg': 'one', 'arg2': 'two'}
>>> kall.args is kall[0]
True
>>> kall.kwargs is kall[1]
True

>>> m = MagicMock()
>>> m.foo(4, 5, 6, arg='two', arg2='three')
```

```
<MagicMock name='mock.foo()' id='...'>
>>> kall = m.mock_calls[0]
>>> name, args, kwargs = kall
>>> name
'foo'
>>> args
(4, 5, 6)
>>> kwargs
{'arg': 'two', 'arg2': 'three'}
>>> name is m.mock_calls[0][0]
True
```

create_autospec

unittest.mock.create_autospec(*spec*, *spec_set*=*False*, *instance*=*False*, ***kwargs*)

Create a mock object using another object as a spec. Attributes on the mock will use the corresponding attribute on the *spec* object as their spec.

Functions or methods being mocked will have their arguments checked to ensure that they are called with the correct signature.

If *spec_set* is `True` then attempting to set attributes that don't exist on the spec object will raise an **`AttributeError`**.

If a class is used as a spec then the return value of the mock (the instance of the class) will have the same spec. You can use a class as the spec for an instance object by passing `instance=True`. The returned mock will only be callable if instances of the mock are callable.

`create_autospec()` also takes arbitrary keyword arguments that are passed to the constructor of the created mock.

See Autospeccing for examples of how to use auto-speccing with **`create_autospec()`** and the *autospec* argument to **`patch()`**.

Changed in version 3.8: **create_autospec()** now returns an **AsyncMock** if the target is an async function.

ANY

unittest.mock.ANY

Sometimes you may need to make assertions about *some* of the arguments in a call to mock, but either not care about some of the arguments or want to pull them individually out of **call_args** and make more complex assertions on them.

To ignore certain arguments you can pass in objects that compare equal to *everything*. Calls to **assert_called_with()** and **assert_called_once_with()** will then succeed no matter what was passed in.

```
>>> mock = Mock(return_value=None)
>>> mock('foo', bar=object())
>>> mock.assert_called_once_with('foo', bar=ANY)
```

ANY can also be used in comparisons with call lists like **mock_calls**:

```
>>> m = MagicMock(return_value=None)
>>> m(1)
>>> m(1, 2)
>>> m(object())
>>> m.mock_calls == [call(1), call(1, 2), ANY]
True
```

FILTER_DIR

unittest.mock.FILTER_DIR

FILTER_DIR is a module level variable that controls the way mock objects respond to **dir()**. The default is `True`, which uses the filtering described below, to only show useful members. If you dislike this filtering, or need to switch it off for diagnostic purposes, then set `mock.FILTER_DIR = False`.

With filtering on, `dir(some_mock)` shows only useful attributes and will include any dynamically created attributes that wouldn't normally be shown. If the mock was created with a *spec* (or *autospec* of course) then all the attributes from the original are shown, even if they haven't been accessed yet:

```
>>> dir(Mock())
['assert_any_call',
 'assert_called',
 'assert_called_once',
 'assert_called_once_with',
 'assert_called_with',
 'assert_has_calls',
 'assert_not_called',
 'attach_mock',
 ...
>>> from urllib import request
>>> dir(Mock(spec=request))
['AbstractBasicAuthHandler',
 'AbstractDigestAuthHandler',
 'AbstractHTTPHandler',
 'BaseHandler',
 ...
```

Many of the not-very-useful (private to **`Mock`** rather than the thing being mocked) underscore and double underscore prefixed attributes have been filtered from the result of calling **`dir()`** on a **`Mock`**. If you dislike this behaviour you can switch it off by setting the module level switch **`FILTER_DIR`**:

```
>>> from unittest import mock
>>> mock.FILTER_DIR = False
>>> dir(mock.Mock())
['_NonCallableMock__get_return_value',
 '_NonCallableMock__get_side_effect',
 '_NonCallableMock__return_value_doc',
 '_NonCallableMock__set_return_value',
 '_NonCallableMock__set_side_effect',
 '__call__',
```

```
'__class__',
...
```

Alternatively you can just use `vars(my_mock)` (instance members) and `dir(type(my_mock))` (type members) to bypass the filtering irrespective of **`mock.FILTER_DIR`**.

mock_open

unittest.mock.mock_open(*mock=None*, *read_data=None*)

A helper function to create a mock to replace the use of **`open()`**. It works for **`open()`** called directly or used as a context manager.

The *mock* argument is the mock object to configure. If `None` (the default) then a **`MagicMock`** will be created for you, with the API limited to methods or attributes available on standard file handles.

read_data is a string for the **`read()`**, **`readline()`**, and **`readlines()`** methods of the file handle to return. Calls to those methods will take data from *read_data* until it is depleted. The mock of these methods is pretty simplistic: every time the *mock* is called, the *read_data* is rewound to the start. If you need more control over the data that you are feeding to the tested code you will need to customize this mock for yourself. When that is insufficient, one of the in-memory filesystem packages on PyPI [https://pypi.org] can offer a realistic filesystem for testing.

Changed in version 3.4: Added **`readline()`** and **`readlines()`** support. The mock of **`read()`** changed to consume *read_data* rather than returning it on each call.

Changed in version 3.5: read_data is now reset on each call to the *mock*.

Changed in version 3.8: Added **`__iter__()`** to implementation so that iteration (such as in for loops) correctly consumes *read_data*.

Using **`open()`** as a context manager is a great way to ensure your file handles are closed properly and is becoming common:

```
with open('/some/path', 'w') as f:
    f.write('something')
```

The issue is that even if you mock out the call to **`open()`** it is the *returned object* that is used as a context manager (and has **`__enter__()`** and **`__exit__()`** called).

Mocking context managers with a **`MagicMock`** is common enough and fiddly enough that a helper function is useful.

```
>>> m = mock_open()
>>> with patch('__main__.open', m):
...     with open('foo', 'w') as h:
...         h.write('some stuff')
...
>>> m.mock_calls
[call('foo', 'w'),
 call().__enter__(),
 call().write('some stuff'),
 call().__exit__(None, None, None)]
>>> m.assert_called_once_with('foo', 'w')
>>> handle = m()
>>> handle.write.assert_called_once_with('some stuff')
```

And for reading files:

```
>>> with patch('__main__.open', mock_open(read_data='bib
...     with open('foo') as h:
...         result = h.read()
...
>>> m.assert_called_once_with('foo')
>>> assert result == 'bibble'
```

Autospeccing

Autospeccing is based on the existing **`spec`** feature of mock. It limits the api of mocks to the api of an original object (the spec),

but it is recursive (implemented lazily) so that attributes of mocks only have the same api as the attributes of the spec. In addition mocked functions / methods have the same call signature as the original so they raise a **`TypeError`** if they are called incorrectly.

Before I explain how auto-speccing works, here's why it is needed.

`Mock` is a very powerful and flexible object, but it suffers from two flaws when used to mock out objects from a system under test. One of these flaws is specific to the **`Mock`** api and the other is a more general problem with using mock objects.

First the problem specific to **`Mock`**. **`Mock`** has two assert methods that are extremely handy: **`assert_called_with()`** and **`assert_called_once_with()`**.

```
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
Traceback (most recent call last):
 ...
AssertionError: Expected 'mock' to be called once. Calle
```

Because mocks auto-create attributes on demand, and allow you to call them with arbitrary arguments, if you misspell one of these assert methods then your assertion is gone:

```
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assret_called_once_with(4, 5, 6)  # Intentional
```

Your tests can pass silently and incorrectly because of the typo.

The second issue is more general to mocking. If you refactor some of your code, rename members and so on, any tests for code that is still using the *old api* but uses mocks instead of the real objects will still pass. This means your tests can all pass even though your code is broken.

Note that this is another reason why you need integration tests as well as unit tests. Testing everything in isolation is all fine and dandy, but if you don't test how your units are "wired together" there is still lots of room for bugs that tests might have caught.

mock already provides a feature to help with this, called speccing. If you use a class or instance as the **spec** for a mock then you can only access attributes on the mock that exist on the real class:

```
>>> from urllib import request
>>> mock = Mock(spec=request.Request)
>>> mock.assret_called_with  # Intentional typo!
Traceback (most recent call last):
 ...
AttributeError: Mock object has no attribute 'assret_cal
```

The spec only applies to the mock itself, so we still have the same issue with any methods on the mock:

```
>>> mock.has_data()
<mock.Mock object at 0x...>
>>> mock.has_data.assret_called_with()  # Intentional ty
```

Auto-speccing solves this problem. You can either pass `autospec=True` to **`patch()`** / **`patch.object()`** or use the **`create_autospec()`** function to create a mock with a spec. If you use the `autospec=True` argument to **`patch()`** then the object that is being replaced will be used as the spec object. Because the speccing is done "lazily" (the spec is created as attributes on the mock are accessed) you can use it with very complex or deeply nested objects (like modules that import modules that import modules) without a big performance hit.

Here's an example of it in use:

```
>>> from urllib import request
>>> patcher = patch('__main__.request', autospec=True)
>>> mock_request = patcher.start()
>>> request is mock_request
True
```

```
>>> mock_request.Request
<MagicMock name='request.Request' spec='Request' id='...
```

You can see that **`request.Request`** has a spec. **`request.Request`** takes two arguments in the constructor (one of which is *self*). Here's what happens if we try to call it incorrectly:

```
>>> req = request.Request()
Traceback (most recent call last):
 ...
TypeError: <lambda>() takes at least 2 arguments (1 give
```

The spec also applies to instantiated classes (i.e. the return value of specced mocks):

```
>>> req = request.Request('foo')
>>> req
<NonCallableMagicMock name='request.Request()' spec='Req
```

`Request` objects are not callable, so the return value of instantiating our mocked out **`request.Request`** is a non-callable mock. With the spec in place any typos in our asserts will raise the correct error:

```
>>> req.add_header('spam', 'eggs')
<MagicMock name='request.Request().add_header()' id='...
>>> req.add_header.assret_called_with  # Intentional typ
Traceback (most recent call last):
 ...
AttributeError: Mock object has no attribute 'assret_cal
>>> req.add_header.assert_called_with('spam', 'eggs')
```

In many cases you will just be able to add `autospec=True` to your existing **`patch()`** calls and then be protected against bugs due to typos and api changes.

As well as using *autospec* through **`patch()`** there is a **`create_autospec()`** for creating autospecced mocks directly:

```
>>> from urllib import request
>>> mock_request = create_autospec(request)
```

```
>>> mock_request.Request('foo', 'bar')
<NonCallableMagicMock name='mock.Request()' spec='Reques
```

This isn't without caveats and limitations however, which is why it is not the default behaviour. In order to know what attributes are available on the spec object, autospec has to introspect (access attributes) the spec. As you traverse attributes on the mock a corresponding traversal of the original object is happening under the hood. If any of your specced objects have properties or descriptors that can trigger code execution then you may not be able to use autospec. On the other hand it is much better to design your objects so that introspection is safe 4.

A more serious problem is that it is common for instance attributes to be created in the **`__init__()`** method and not to exist on the class at all. *autospec* can't know about any dynamically created attributes and restricts the api to visible attributes.

```
>>> class Something:
...   def __init__(self):
...     self.a = 33
...
>>> with patch('__main__.Something', autospec=True):
...   thing = Something()
...   thing.a
...
Traceback (most recent call last):
  ...
AttributeError: Mock object has no attribute 'a'
```

There are a few different ways of resolving this problem. The easiest, but not necessarily the least annoying, way is to simply set the required attributes on the mock after creation. Just because *autospec* doesn't allow you to fetch attributes that don't exist on the spec it doesn't prevent you setting them:

```
>>> with patch('__main__.Something', autospec=True):
...   thing = Something()
...   thing.a = 33
...
```

There is a more aggressive version of both *spec* and *autospec* that *does* prevent you setting non-existent attributes. This is useful if you want to ensure your code only *sets* valid attributes too, but obviously it prevents this particular scenario:

```
>>> with patch('__main__.Something', autospec=True, spec
...    thing = Something()
...    thing.a = 33
...
Traceback (most recent call last):
  ...
AttributeError: Mock object has no attribute 'a'
```

Probably the best way of solving the problem is to add class attributes as default values for instance members initialised in **`__init__()`**. Note that if you are only setting default attributes in **`__init__()`** then providing them via class attributes (shared between instances of course) is faster too. e.g.

```
class Something:
    a = 33
```

This brings up another issue. It is relatively common to provide a default value of `None` for members that will later be an object of a different type. `None` would be useless as a spec because it wouldn't let you access *any* attributes or methods on it. As `None` is *never* going to be useful as a spec, and probably indicates a member that will normally of some other type, autospec doesn't use a spec for members that are set to `None`. These will just be ordinary mocks (well - MagicMocks):

```
>>> class Something:
...     member = None
...
>>> mock = create_autospec(Something)
>>> mock.member.foo.bar.baz()
<MagicMock name='mock.member.foo.bar.baz()' id='...'>
```

If modifying your production classes to add defaults isn't to your liking then there are more options. One of these is simply to use an

instance as the spec rather than the class. The other is to create a subclass of the production class and add the defaults to the subclass without affecting the production class. Both of these require you to use an alternative object as the spec. Thankfully **`patch()`** supports this - you can simply pass the alternative object as the *autospec* argument:

```
>>> class Something:
...   def __init__(self):
...     self.a = 33
...
>>> class SomethingForTest(Something):
...   a = 33
...
>>> p = patch('__main__.Something', autospec=SomethingFo
>>> mock = p.start()
>>> mock.a
<NonCallableMagicMock name='Something.a' spec='int' id='
```

4

This only applies to classes or already instantiated objects. Calling a mocked class to create a mock instance *does not* create a real instance. It is only attribute lookups - along with calls to **`dir()`** - that are done.

Sealing mocks

unittest.mock.seal(*mock*)

Seal will disable the automatic creation of mocks when accessing an attribute of the mock being sealed or any of its attributes that are already mocks recursively.

If a mock instance with a name or a spec is assigned to an attribute it won't be considered in the sealing chain. This allows one to prevent seal from fixing part of the mock object.

```
>>> mock = Mock()
>>> mock.submock.attribute1 = 2
```

```
>>> mock.not_submock = mock.Mock(name="sample_name"
>>> seal(mock)
>>> mock.new_attribute  # This will raise Attribute
>>> mock.submock.attribute2  # This will raise Attr
>>> mock.not_submock.attribute2  # This won't raise
```

New in version 3.7.

`unittest.mock` — getting started

New in version 3.3.

Using Mock

Mock Patching Methods

Common uses for `Mock` objects include:

- Patching methods
- Recording method calls on objects

You might want to replace a method on an object to check that it is called with the correct arguments by another part of the system:

```
>>> real = SomeClass()
>>> real.method = MagicMock(name='method')
>>> real.method(3, 4, 5, key='value')
<MagicMock name='method()' id='...'>
```

Once our mock has been used (`real.method` in this example) it has methods and attributes that allow you to make assertions about how it has been used.

Note

In most of these examples the `Mock` and `MagicMock` classes are interchangeable. As the `MagicMock` is the more capable class it makes a sensible one to use by default.

Once the mock has been called its `called` attribute is set to `True`. More importantly we can use the `assert_called_with()` or

`assert_called_once_with()` method to check that it was called with the correct arguments.

This example tests that calling `ProductionClass().method` results in a call to the `something` method:

```
>>> class ProductionClass:
...     def method(self):
...         self.something(1, 2, 3)
...     def something(self, a, b, c):
...         pass
...
>>> real = ProductionClass()
>>> real.something = MagicMock()
>>> real.method()
>>> real.something.assert_called_once_with(1, 2, 3)
```

Mock for Method Calls on an Object

In the last example we patched a method directly on an object to check that it was called correctly. Another common use case is to pass an object into a method (or some part of the system under test) and then check that it is used in the correct way.

The simple `ProductionClass` below has a `closer` method. If it is called with an object then it calls `close` on it.

```
>>> class ProductionClass:
...     def closer(self, something):
...         something.close()
...
```

So to test it we need to pass in an object with a `close` method and check that it was called correctly.

```
>>> real = ProductionClass()
>>> mock = Mock()
>>> real.closer(mock)
>>> mock.close.assert_called_with()
```

We don't have to do any work to provide the 'close' method on our mock. Accessing close creates it. So, if 'close' hasn't already been called then accessing it in the test will create it, but **`assert_called_with()`** will raise a failure exception.

Mocking Classes

A common use case is to mock out classes instantiated by your code under test. When you patch a class, then that class is replaced with a mock. Instances are created by *calling the class*. This means you access the "mock instance" by looking at the return value of the mocked class.

In the example below we have a function `some_function` that instantiates `Foo` and calls a method on it. The call to **`patch()`** replaces the class `Foo` with a mock. The `Foo` instance is the result of calling the mock, so it is configured by modifying the mock **`return_value`**.

```
>>> def some_function():
...     instance = module.Foo()
...     return instance.method()
...
>>> with patch('module.Foo') as mock:
...     instance = mock.return_value
...     instance.method.return_value = 'the result'
...     result = some_function()
...     assert result == 'the result'
```

Naming your mocks

It can be useful to give your mocks a name. The name is shown in the repr of the mock and can be helpful when the mock appears in test failure messages. The name is also propagated to attributes or methods of the mock:

```
>>> mock = MagicMock(name='foo')
>>> mock
<MagicMock name='foo' id='...'>
>>> mock.method
```

```
<MagicMock name='foo.method' id='...'>
```

Tracking all Calls

Often you want to track more than a single call to a method. The **`mock_calls`** attribute records all calls to child attributes of the mock - and also to their children.

```
>>> mock = MagicMock()
>>> mock.method()
<MagicMock name='mock.method()' id='...'>
>>> mock.attribute.method(10, x=53)
<MagicMock name='mock.attribute.method()' id='...'>
>>> mock.mock_calls
[call.method(), call.attribute.method(10, x=53)]
```

If you make an assertion about `mock_calls` and any unexpected methods have been called, then the assertion will fail. This is useful because as well as asserting that the calls you expected have been made, you are also checking that they were made in the right order and with no additional calls:

You use the **`call`** object to construct lists for comparing with `mock_calls`:

```
>>> expected = [call.method(), call.attribute.method(10,
>>> mock.mock_calls == expected
True
```

However, parameters to calls that return mocks are not recorded, which means it is not possible to track nested calls where the parameters used to create ancestors are important:

```
>>> m = Mock()
>>> m.factory(important=True).deliver()
<Mock name='mock.factory().deliver()' id='...'>
>>> m.mock_calls[-1] == call.factory(important=False).de
True
```

Setting Return Values and Attributes

Setting the return values on a mock object is trivially easy:

```
>>> mock = Mock()
>>> mock.return_value = 3
>>> mock()
3
```

Of course you can do the same for methods on the mock:

```
>>> mock = Mock()
>>> mock.method.return_value = 3
>>> mock.method()
3
```

The return value can also be set in the constructor:

```
>>> mock = Mock(return_value=3)
>>> mock()
3
```

If you need an attribute setting on your mock, just do it:

```
>>> mock = Mock()
>>> mock.x = 3
>>> mock.x
3
```

Sometimes you want to mock up a more complex situation, like for example `mock.connection.cursor().execute("SELECT 1")`. If we wanted this call to return a list, then we have to configure the result of the nested call.

We can use **`call`** to construct the set of calls in a "chained call" like this for easy assertion afterwards:

```
>>> mock = Mock()
>>> cursor = mock.connection.cursor.return_value
>>> cursor.execute.return_value = ['foo']
>>> mock.connection.cursor().execute("SELECT 1")
['foo']
>>> expected = call.connection.cursor().execute("SELECT
```

```
>>> mock.mock_calls
[call.connection.cursor(), call.connection.cursor().exec
>>> mock.mock_calls == expected
True
```

It is the call to `.call_list()` that turns our call object into a list of calls representing the chained calls.

Raising exceptions with mocks

A useful attribute is **`side_effect`**. If you set this to an exception class or instance then the exception will be raised when the mock is called.

```
>>> mock = Mock(side_effect=Exception('Boom!'))
>>> mock()
Traceback (most recent call last):
  ...
Exception: Boom!
```

Side effect functions and iterables

`side_effect` can also be set to a function or an iterable. The use case for `side_effect` as an iterable is where your mock is going to be called several times, and you want each call to return a different value. When you set `side_effect` to an iterable every call to the mock returns the next value from the iterable:

```
>>> mock = MagicMock(side_effect=[4, 5, 6])
>>> mock()
4
>>> mock()
5
>>> mock()
6
```

For more advanced use cases, like dynamically varying the return values depending on what the mock is called with, `side_effect` can be a function. The function will be called with the same arguments as the mock. Whatever the function returns is what the

call returns:

```
>>> vals = {(1, 2): 1, (2, 3): 2}
>>> def side_effect(*args):
...     return vals[args]
...
>>> mock = MagicMock(side_effect=side_effect)
>>> mock(1, 2)
1
>>> mock(2, 3)
2
```

Mocking asynchronous iterators

Since Python 3.8, `AsyncMock` and `MagicMock` have support to mock Asynchronous Iterators through `__aiter__`. The **`return_value`** attribute of `__aiter__` can be used to set the return values to be used for iteration.

```
>>> mock = MagicMock()  # AsyncMock also works here
>>> mock.__aiter__.return_value = [1, 2, 3]
>>> async def main():
...     return [i async for i in mock]
...
>>> asyncio.run(main())
[1, 2, 3]
```

Mocking asynchronous context manager

Since Python 3.8, `AsyncMock` and `MagicMock` have support to mock Asynchronous Context Managers through `__aenter__` and `__aexit__`. By default, `__aenter__` and `__aexit__` are `AsyncMock` instances that return an async function.

```
>>> class AsyncContextManager:
...     async def __aenter__(self):
...         return self
...     async def __aexit__(self, exc_type, exc, tb):
...         pass
```

```
...
>>> mock_instance = MagicMock(AsyncContextManager())   #
>>> async def main():
...     async with mock_instance as result:
...         pass
...
>>> asyncio.run(main())
>>> mock_instance.__aenter__.assert_awaited_once()
>>> mock_instance.__aexit__.assert_awaited_once()
```

Creating a Mock from an Existing Object

One problem with over use of mocking is that it couples your tests to the implementation of your mocks rather than your real code. Suppose you have a class that implements `some_method`. In a test for another class, you provide a mock of this object that *also* provides `some_method`. If later you refactor the first class, so that it no longer has `some_method` - then your tests will continue to pass even though your code is now broken!

`Mock` allows you to provide an object as a specification for the mock, using the *spec* keyword argument. Accessing methods / attributes on the mock that don't exist on your specification object will immediately raise an attribute error. If you change the implementation of your specification, then tests that use that class will start failing immediately without you having to instantiate the class in those tests.

```
>>> mock = Mock(spec=SomeClass)
>>> mock.old_method()
Traceback (most recent call last):
   ...
AttributeError: object has no attribute 'old_method'
```

Using a specification also enables a smarter matching of calls made to the mock, regardless of whether some parameters were passed as positional or named arguments:

```
>>> def f(a, b, c): pass
...
```

```
>>> mock = Mock(spec=f)
>>> mock(1, 2, 3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(a=1, b=2, c=3)
```

If you want this smarter matching to also work with method calls on the mock, you can use auto-speccing.

If you want a stronger form of specification that prevents the setting of arbitrary attributes as well as the getting of them then you can use *spec_set* instead of *spec*.

Patch Decorators

Note

With **`patch()`** it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read where to patch.

A common need in tests is to patch a class attribute or a module attribute, for example patching a builtin or patching a class in a module to test that it is instantiated. Modules and classes are effectively global, so patching on them has to be undone after the test or the patch will persist into other tests and cause hard to diagnose problems.

mock provides three convenient decorators for this: **`patch()`**, **`patch.object()`** and **`patch.dict()`**. `patch` takes a single string, of the form `package.module.Class.attribute` to specify the attribute you are patching. It also optionally takes a value that you want the attribute (or class or whatever) to be replaced with. 'patch.object' takes an object and the name of the attribute you would like patched, plus optionally the value to patch it with.

`patch.object`:

```
>>> original = SomeClass.attribute
```

```
>>> @patch.object(SomeClass, 'attribute', sentinel.attri
... def test():
...     assert SomeClass.attribute == sentinel.attribute
...
>>> test()
>>> assert SomeClass.attribute == original

>>> @patch('package.module.attribute', sentinel.attribut
... def test():
...     from package.module import attribute
...     assert attribute is sentinel.attribute
...
>>> test()
```

If you are patching a module (including **`builtins`**) then use **`patch()`** instead of **`patch.object()`**:

```
>>> mock = MagicMock(return_value=sentinel.file_handle)
>>> with patch('builtins.open', mock):
...     handle = open('filename', 'r')
...
>>> mock.assert_called_with('filename', 'r')
>>> assert handle == sentinel.file_handle, "incorrect fi
```

The module name can be 'dotted', in the form `package.module` if needed:

```
>>> @patch('package.module.ClassName.attribute', sentine
... def test():
...     from package.module import ClassName
...     assert ClassName.attribute == sentinel.attribute
...
>>> test()
```

A nice pattern is to actually decorate test methods themselves:

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'attribute', sentinel.a
...     def test_something(self):
...         self.assertEqual(SomeClass.attribute, sentin
```

```
...
>>> original = SomeClass.attribute
>>> MyTest('test_something').test_something()
>>> assert SomeClass.attribute == original
```

If you want to patch with a Mock, you can use **`patch()`** with only one argument (or **`patch.object()`** with two arguments). The mock will be created for you and passed into the test function / method:

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'static_method')
...     def test_something(self, mock_method):
...         SomeClass.static_method()
...         mock_method.assert_called_with()
...
>>> MyTest('test_something').test_something()
```

You can stack up multiple patch decorators using this pattern:

```
>>> class MyTest(unittest.TestCase):
...     @patch('package.module.ClassName1')
...     @patch('package.module.ClassName2')
...     def test_something(self, MockClass2, MockClass1)
...         self.assertIs(package.module.ClassName1, Moc
...         self.assertIs(package.module.ClassName2, Moc
...
>>> MyTest('test_something').test_something()
```

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal *Python* order that decorators are applied). This means from the bottom up, so in the example above the mock for `test_module.ClassName2` is passed in first.

There is also **`patch.dict()`** for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```
>>> foo = {'key': 'value'}
```

```
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=T
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

`patch`, `patch.object` and `patch.dict` can all be used as context managers.

Where you use **`patch()`** to create a mock for you, you can get a reference to the mock using the "as" form of the with statement:

```
>>> class ProductionClass:
...     def method(self):
...         pass
...
>>> with patch.object(ProductionClass, 'method') as mock
...     mock_method.return_value = None
...     real = ProductionClass()
...     real.method(1, 2, 3)
...
>>> mock_method.assert_called_with(1, 2, 3)
```

As an alternative `patch`, `patch.object` and `patch.dict` can be used as class decorators. When used in this way it is the same as applying the decorator individually to every method whose name starts with "test".

Further Examples

Here are some more examples for some slightly more advanced scenarios.

Mocking chained calls

Mocking chained calls is actually straightforward with mock once you understand the **`return_value`** attribute. When a mock is called for the first time, or you fetch its `return_value` before it has been called, a new **`Mock`** is created.

This means that you can see how the object returned from a call to a mocked object has been used by interrogating the `return_value` mock:

```
>>> mock = Mock()
>>> mock().foo(a=2, b=3)
<Mock name='mock().foo()' id='...'>
>>> mock.return_value.foo.assert_called_with(a=2, b=3)
```

From here it is a simple step to configure and then make assertions about chained calls. Of course another alternative is writing your code in a more testable way in the first place…

So, suppose we have some code that looks a little bit like this:

```
>>> class Something:
...     def __init__(self):
...         self.backend = BackendProvider()
...     def method(self):
...         response = self.backend.get_endpoint('foobar
...         # more code
```

Assuming that `BackendProvider` is already well tested, how do we test `method()`? Specifically, we want to test that the code section `# more code` uses the response object in the correct way.

As this chain of calls is made from an instance attribute we can monkey patch the `backend` attribute on a `Something` instance. In this particular case we are only interested in the return value from the final call to `start_call` so we don't have much configuration to do. Let's assume the object it returns is 'file-like', so we'll ensure that our response object uses the builtin **`open()`** as its `spec`.

To do this we create a mock instance as our mock backend and create a mock response object for it. To set the response as the return value for that final `start_call` we could do this:

```
mock_backend.get_endpoint.return_value.create_call.retur
```

We can do that in a slightly nicer way using the

configure_mock() method to directly set the return value for us:

```
>>> something = Something()
>>> mock_response = Mock(spec=open)
>>> mock_backend = Mock()
>>> config = {'get_endpoint.return_value.create_call.ret
>>> mock_backend.configure_mock(**config)
```

With these we monkey patch the "mock backend" in place and can make the real call:

```
>>> something.backend = mock_backend
>>> something.method()
```

Using **mock_calls** we can check the chained call with a single assert. A chained call is several calls in one line of code, so there will be several entries in `mock_calls`. We can use **call.call_list()** to create this list of calls for us:

```
>>> chained = call.get_endpoint('foobar').create_call('s
>>> call_list = chained.call_list()
>>> assert mock_backend.mock_calls == call_list
```

Partial mocking

In some tests I wanted to mock out a call to **datetime.date.today()** to return a known date, but I didn't want to prevent the code under test from creating new date objects. Unfortunately **datetime.date** is written in C, and so I couldn't just monkey-patch out the static **date.today()** method.

I found a simple way of doing this that involved effectively wrapping the date class with a mock, but passing through calls to the constructor to the real class (and returning real instances).

The **patch decorator** is used here to mock out the `date` class in the module under test. The **side_effect** attribute on the mock date class is then set to a lambda function that returns a real date. When the mock date class is called a real date will be constructed and returned by `side_effect`.

```
>>> from datetime import date
>>> with patch('mymodule.date') as mock_date:
...     mock_date.today.return_value = date(2010, 10, 8)
...     mock_date.side_effect = lambda *args, **kw: date
...
...     assert mymodule.date.today() == date(2010, 10, 8
...     assert mymodule.date(2009, 6, 8) == date(2009, 6
```

Note that we don't patch **`datetime.date`** globally, we patch `date` in the module that *uses* it. See where to patch.

When `date.today()` is called a known date is returned, but calls to the `date(...)` constructor still return normal dates. Without this you can find yourself having to calculate an expected result using exactly the same algorithm as the code under test, which is a classic testing anti-pattern.

Calls to the date constructor are recorded in the `mock_date` attributes (`call_count` and friends) which may also be useful for your tests.

An alternative way of dealing with mocking dates, or other builtin classes, is discussed in this blog entry [https://williambert.online/2011/07/how-to-unit-testing-in-django-with-mocking-and-patching/].

Mocking a Generator Method

A Python generator is a function or method that uses the **`yield`** statement to return a series of values when iterated over 1.

A generator method / function is called to return the generator object. It is the generator object that is then iterated over. The protocol method for iteration is **`__iter__()`**, so we can mock this using a **`MagicMock`**.

Here's an example class with an "iter" method implemented as a generator:

```
>>> class Foo:
...     def iter(self):
...         for i in [1, 2, 3]:
```

```
...             yield i
...
>>> foo = Foo()
>>> list(foo.iter())
[1, 2, 3]
```

How would we mock this class, and in particular its "iter" method?

To configure the values returned from the iteration (implicit in the call to `list`), we need to configure the object returned by the call to `foo.iter()`.

```
>>> mock_foo = MagicMock()
>>> mock_foo.iter.return_value = iter([1, 2, 3])
>>> list(mock_foo.iter())
[1, 2, 3]
```

1

There are also generator expressions and more advanced uses [http://www.dabeaz.com/coroutines/index.html] of generators, but we aren't concerned about them here. A very good introduction to generators and how powerful they are is: Generator Tricks for Systems Programmers [http://www.dabeaz.com/generators/].

Applying the same patch to every test method

If you want several patches in place for multiple test methods the obvious way is to apply the patch decorators to every method. This can feel like unnecessary repetition. Instead, you can use `patch()` (in all its various forms) as a class decorator. This applies the patches to all test methods on the class. A test method is identified by methods whose names start with `test`:

```
>>> @patch('mymodule.SomeClass')
... class MyTest(unittest.TestCase):
...
...     def test_one(self, MockSomeClass):
...         self.assertIs(mymodule.SomeClass, MockSomeCl
...
...     def test_two(self, MockSomeClass):
```

```
...         self.assertIs(mymodule.SomeClass, MockSomeCl
...
...     def not_a_test(self):
...         return 'something'
...
>>> MyTest('test_one').test_one()
>>> MyTest('test_two').test_two()
>>> MyTest('test_two').not_a_test()
'something'
```

An alternative way of managing patches is to use the patch methods: start and stop. These allow you to move the patching into your `setUp` and `tearDown` methods.

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         self.patcher = patch('mymodule.foo')
...         self.mock_foo = self.patcher.start()
...
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
...     def tearDown(self):
...         self.patcher.stop()
...
>>> MyTest('test_foo').run()
```

If you use this technique you must ensure that the patching is "undone" by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the setUp then tearDown is not called. **`unittest.TestCase.addCleanup()`** makes this easier:

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('mymodule.foo')
...         self.addCleanup(patcher.stop)
...         self.mock_foo = patcher.start()
...
```

```
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
>>> MyTest('test_foo').run()
```

Mocking Unbound Methods

Whilst writing tests today I needed to patch an *unbound method* (patching the method on the class rather than on the instance). I needed self to be passed in as the first argument because I want to make asserts about which objects were calling this particular method. The issue is that you can't patch with a mock for this, because if you replace an unbound method with a mock it doesn't become a bound method when fetched from the instance, and so it doesn't get self passed in. The workaround is to patch the unbound method with a real function instead. The `patch()` decorator makes it so simple to patch out methods with a mock that having to create a real function becomes a nuisance.

If you pass `autospec=True` to patch then it does the patching with a *real* function object. This function object has the same signature as the one it is replacing, but delegates to a mock under the hood. You still get your mock auto-created in exactly the same way as before. What it means though, is that if you use it to patch out an unbound method on a class the mocked function will be turned into a bound method if it is fetched from an instance. It will have `self` passed in as the first argument, which is exactly what I wanted:

```
>>> class Foo:
...   def foo(self):
...     pass
...
>>> with patch.object(Foo, 'foo', autospec=True) as mock
...   mock_foo.return_value = 'foo'
...   foo = Foo()
...   foo.foo()
...
'foo'
>>> mock_foo.assert_called_once_with(foo)
```

If we don't use `autospec=True` then the unbound method is patched out with a Mock instance instead, and isn't called with `self`.

Checking multiple calls with mock

mock has a nice API for making assertions about how your mock objects are used.

```
>>> mock = Mock()
>>> mock.foo_bar.return_value = None
>>> mock.foo_bar('baz', spam='eggs')
>>> mock.foo_bar.assert_called_with('baz', spam='eggs')
```

If your mock is only being called once you can use the **`assert_called_once_with()`** method that also asserts that the **`call_count`** is one.

```
>>> mock.foo_bar.assert_called_once_with('baz', spam='eg
>>> mock.foo_bar()
>>> mock.foo_bar.assert_called_once_with('baz', spam='eg
Traceback (most recent call last):
    ...
AssertionError: Expected to be called once. Called 2 tim
```

Both `assert_called_with` and `assert_called_once_with` make assertions about the *most recent* call. If your mock is going to be called several times, and you want to make assertions about *all* those calls you can use **`call_args_list`**:

```
>>> mock = Mock(return_value=None)
>>> mock(1, 2, 3)
>>> mock(4, 5, 6)
>>> mock()
>>> mock.call_args_list
[call(1, 2, 3), call(4, 5, 6), call()]
```

The **`call`** helper makes it easy to make assertions about these calls. You can build up a list of expected calls and compare it to `call_args_list`. This looks remarkably similar to the repr of the

`call_args_list`:

```
>>> expected = [call(1, 2, 3), call(4, 5, 6), call()]
>>> mock.call_args_list == expected
True
```

Coping with mutable arguments

Another situation is rare, but can bite you, is when your mock is called with mutable arguments. `call_args` and `call_args_list` store *references* to the arguments. If the arguments are mutated by the code under test then you can no longer make assertions about what the values were when the mock was called.

Here's some example code that shows the problem. Imagine the following functions defined in 'mymodule':

```
def frob(val):
    pass

def grob(val):
    "First frob and then clear val"
    frob(val)
    val.clear()
```

When we try to test that `grob` calls `frob` with the correct argument look what happens:

```
>>> with patch('mymodule.frob') as mock_frob:
...     val = {6}
...     mymodule.grob(val)
...
>>> val
set()
>>> mock_frob.assert_called_with({6})
Traceback (most recent call last):
    ...
AssertionError: Expected: (({6},), {})
Called with: ((set(),), {})
```

One possibility would be for mock to copy the arguments you pass in. This could then cause problems if you do assertions that rely on object identity for equality.

Here's one solution that uses the **`side_effect`** functionality. If you provide a `side_effect` function for a mock then `side_effect` will be called with the same args as the mock. This gives us an opportunity to copy the arguments and store them for later assertions. In this example I'm using *another* mock to store the arguments so that I can use the mock methods for doing the assertion. Again a helper function sets this up for me.

```
>>> from copy import deepcopy
>>> from unittest.mock import Mock, patch, DEFAULT
>>> def copy_call_args(mock):
...     new_mock = Mock()
...     def side_effect(*args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         new_mock(*args, **kwargs)
...         return DEFAULT
...     mock.side_effect = side_effect
...     return new_mock
...
>>> with patch('mymodule.frob') as mock_frob:
...     new_mock = copy_call_args(mock_frob)
...     val = {6}
...     mymodule.grob(val)
...
>>> new_mock.assert_called_with({6})
>>> new_mock.call_args
call({6})
```

`copy_call_args` is called with the mock that will be called. It returns a new mock that we do the assertion on. The `side_effect` function makes a copy of the args and calls our `new_mock` with the copy.

Note

If your mock is only going to be used once there is an easier way of checking arguments at the point they are called. You can simply do the checking inside a `side_effect` function.

```
>>> def side_effect(arg):
...     assert arg == {6}
...
>>> mock = Mock(side_effect=side_effect)
>>> mock({6})
>>> mock(set())
Traceback (most recent call last):
    ...
AssertionError
```

An alternative approach is to create a subclass of **`Mock`** or **`MagicMock`** that copies (using **`copy.deepcopy()`**) the arguments. Here's an example implementation:

```
>>> from copy import deepcopy
>>> class CopyingMock(MagicMock):
...     def __call__(self, /, *args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         return super().__call__(*args, **kwargs)
...
>>> c = CopyingMock(return_value=None)
>>> arg = set()
>>> c(arg)
>>> arg.add(1)
>>> c.assert_called_with(set())
>>> c.assert_called_with(arg)
Traceback (most recent call last):
    ...
AssertionError: Expected call: mock({1})
Actual call: mock(set())
>>> c.foo
<CopyingMock name='mock.foo' id='...'>
```

When you subclass `Mock` or `MagicMock` all dynamically created

attributes, and the `return_value` will use your subclass automatically. That means all children of a `CopyingMock` will also have the type `CopyingMock`.

Nesting Patches

Using patch as a context manager is nice, but if you do multiple patches you can end up with nested with statements indenting further and further to the right:

```
>>> class MyTest(unittest.TestCase):
...
...     def test_foo(self):
...         with patch('mymodule.Foo') as mock_foo:
...             with patch('mymodule.Bar') as mock_bar:
...                 with patch('mymodule.Spam') as mock_
...                     assert mymodule.Foo is mock_foo
...                     assert mymodule.Bar is mock_bar
...                     assert mymodule.Spam is mock_spa
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').test_foo()
>>> assert mymodule.Foo is original
```

With unittest `cleanup` functions and the patch methods: start and stop we can achieve the same effect without the nested indentation. A simple helper method, `create_patch`, puts the patch in place and returns the created mock for us:

```
>>> class MyTest(unittest.TestCase):
...
...     def create_patch(self, name):
...         patcher = patch(name)
...         thing = patcher.start()
...         self.addCleanup(patcher.stop)
...         return thing
...
...     def test_foo(self):
...         mock_foo = self.create_patch('mymodule.Foo')
```

```
...         mock_bar = self.create_patch('mymodule.Bar')
...         mock_spam = self.create_patch('mymodule.Spam
...
...         assert mymodule.Foo is mock_foo
...         assert mymodule.Bar is mock_bar
...         assert mymodule.Spam is mock_spam
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').run()
>>> assert mymodule.Foo is original
```

Mocking a dictionary with MagicMock

You may want to mock a dictionary, or other container object, recording all access to it whilst having it still behave like a dictionary.

We can do this with **`MagicMock`**, which will behave like a dictionary, and using **`side_effect`** to delegate dictionary access to a real underlying dictionary that is under our control.

When the **`__getitem__()`** and **`__setitem__()`** methods of our `MagicMock` are called (normal dictionary access) then `side_effect` is called with the key (and in the case of `__setitem__` the value too). We can also control what is returned.

After the `MagicMock` has been used we can use attributes like **`call_args_list`** to assert about how the dictionary was used:

```
>>> my_dict = {'a': 1, 'b': 2, 'c': 3}
>>> def getitem(name):
...      return my_dict[name]
...
>>> def setitem(name, val):
...     my_dict[name] = val
...
>>> mock = MagicMock()
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

Note

An alternative to using `MagicMock` is to use `Mock` and *only* provide the magic methods you specifically want:

```
>>> mock = Mock()
>>> mock.__getitem__ = Mock(side_effect=getitem)
>>> mock.__setitem__ = Mock(side_effect=setitem)
```

A *third* option is to use `MagicMock` but passing in `dict` as the *spec* (or *spec_set*) argument so that the `MagicMock` created only has dictionary magic methods available:

```
>>> mock = MagicMock(spec_set=dict)
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

With these side effect functions in place, the `mock` will behave like a normal dictionary but recording the access. It even raises a **`KeyError`** if you try to access a key that doesn't exist.

```
>>> mock['a']
1
>>> mock['c']
3
>>> mock['d']
Traceback (most recent call last):
    ...
KeyError: 'd'
>>> mock['b'] = 'fish'
>>> mock['d'] = 'eggs'
>>> mock['b']
'fish'
>>> mock['d']
'eggs'
```

After it has been used you can make assertions about the access using the normal mock methods and attributes:

```
>>> mock.__getitem__.call_args_list
```

```
[call('a'), call('c'), call('d'), call('b'), call('d')]
>>> mock.__setitem__.call_args_list
[call('b', 'fish'), call('d', 'eggs')]
>>> my_dict
{'a': 1, 'b': 'fish', 'c': 3, 'd': 'eggs'}
```

Mock subclasses and their attributes

There are various reasons why you might want to subclass **`Mock`**. One reason might be to add helper methods. Here's a silly example:

```
>>> class MyMock(MagicMock):
...     def has_been_called(self):
...         return self.called
...
>>> mymock = MyMock(return_value=None)
>>> mymock
<MyMock id='...'>
>>> mymock.has_been_called()
False
>>> mymock()
>>> mymock.has_been_called()
True
```

The standard behaviour for `Mock` instances is that attributes and the return value mocks are of the same type as the mock they are accessed on. This ensures that `Mock` attributes are `Mocks` and `MagicMock` attributes are `MagicMocks` 2. So if you're subclassing to add helper methods then they'll also be available on the attributes and return value mock of instances of your subclass.

```
>>> mymock.foo
<MyMock name='mock.foo' id='...'>
>>> mymock.foo.has_been_called()
False
>>> mymock.foo()
<MyMock name='mock.foo()' id='...'>
>>> mymock.foo.has_been_called()
True
```

Sometimes this is inconvenient. For example, one user [https://code.google.com/archive/p/mock/issues/105] is subclassing mock to created a Twisted adaptor [https://twistedmatrix.com/documents/11.0.0/api/twisted.python.components.html]. Having this applied to attributes too actually causes errors.

`Mock` (in all its flavours) uses a method called `_get_child_mock` to create these "sub-mocks" for attributes and return values. You can prevent your subclass being used for attributes by overriding this method. The signature is that it takes arbitrary keyword arguments (`**kwargs`) which are then passed onto the mock constructor:

```
>>> class Subclass(MagicMock):
...     def _get_child_mock(self, /, **kwargs):
...         return MagicMock(**kwargs)
...
>>> mymock = Subclass()
>>> mymock.foo
<MagicMock name='mock.foo' id='...'>
>>> assert isinstance(mymock, Subclass)
>>> assert not isinstance(mymock.foo, Subclass)
>>> assert not isinstance(mymock(), Subclass)
```

2

An exception to this rule are the non-callable mocks. Attributes use the callable variant because otherwise non-callable mocks couldn't have callable methods.

Mocking imports with patch.dict

One situation where mocking can be hard is where you have a local import inside a function. These are harder to mock because they aren't using an object from the module namespace that we can patch out.

Generally local imports are to be avoided. They are sometimes done to prevent circular dependencies, for which there is *usually* a much better way to solve the problem (refactor the code) or to prevent "up front costs" by delaying the import. This can also be solved in

better ways than an unconditional local import (store the module as a class or module attribute and only do the import on first use).

That aside there is a way to use `mock` to affect the results of an import. Importing fetches an *object* from the **`sys.modules`** dictionary. Note that it fetches an *object*, which need not be a module. Importing a module for the first time results in a module object being put in `sys.modules`, so usually when you import something you get a module back. This need not be the case however.

This means you can use **`patch.dict()`** to *temporarily* put a mock in place in **`sys.modules`**. Any imports whilst this patch is active will fetch the mock. When the patch is complete (the decorated function exits, the with statement body is complete or `patcher.stop()` is called) then whatever was there previously will be restored safely.

Here's an example that mocks out the 'fooble' module.

```
>>> import sys
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     import fooble
...     fooble.blob()
...
<Mock name='mock.blob()' id='...'>
>>> assert 'fooble' not in sys.modules
>>> mock.blob.assert_called_once_with()
```

As you can see the `import fooble` succeeds, but on exit there is no 'fooble' left in **`sys.modules`**.

This also works for the `from module import name` form:

```
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     from fooble import blob
...     blob.blip()
...
```

```
<Mock name='mock.blob.blip()' id='...'>
>>> mock.blob.blip.assert_called_once_with()
```

With slightly more work you can also mock package imports:

```
>>> mock = Mock()
>>> modules = {'package': mock, 'package.module': mock.m
>>> with patch.dict('sys.modules', modules):
...     from package.module import fooble
...     fooble()
...
<Mock name='mock.module.fooble()' id='...'>
>>> mock.module.fooble.assert_called_once_with()
```

Tracking order of calls and less verbose call assertions

The **`Mock`** class allows you to track the *order* of method calls on your mock objects through the **`method_calls`** attribute. This doesn't allow you to track the order of calls between separate mock objects, however we can use **`mock_calls`** to achieve the same effect.

Because mocks track calls to child mocks in `mock_calls`, and accessing an arbitrary attribute of a mock creates a child mock, we can create our separate mocks from a parent one. Calls to those child mock will then all be recorded, in order, in the `mock_calls` of the parent:

```
>>> manager = Mock()
>>> mock_foo = manager.foo
>>> mock_bar = manager.bar

>>> mock_foo.something()
<Mock name='mock.foo.something()' id='...'>
>>> mock_bar.other.thing()
<Mock name='mock.bar.other.thing()' id='...'>

>>> manager.mock_calls
[call.foo.something(), call.bar.other.thing()]
```

We can then assert about the calls, including the order, by comparing with the `mock_calls` attribute on the manager mock:

```
>>> expected_calls = [call.foo.something(), call.bar.oth
>>> manager.mock_calls == expected_calls
True
```

If `patch` is creating, and putting in place, your mocks then you can attach them to a manager mock using the **`attach_mock()`** method. After attaching calls will be recorded in `mock_calls` of the manager.

```
>>> manager = MagicMock()
>>> with patch('mymodule.Class1') as MockClass1:
...     with patch('mymodule.Class2') as MockClass2:
...         manager.attach_mock(MockClass1, 'MockClass1'
...         manager.attach_mock(MockClass2, 'MockClass2'
...         MockClass1().foo()
...         MockClass2().bar()
<MagicMock name='mock.MockClass1().foo()' id='...'>
<MagicMock name='mock.MockClass2().bar()' id='...'>
>>> manager.mock_calls
[call.MockClass1(),
call.MockClass1().foo(),
call.MockClass2(),
call.MockClass2().bar()]
```

If many calls have been made, but you're only interested in a particular sequence of them then an alternative is to use the **`assert_has_calls()`** method. This takes a list of calls (constructed with the **`call`** object). If that sequence of calls are in **`mock_calls`** then the assert succeeds.

```
>>> m = MagicMock()
>>> m().foo().bar().baz()
<MagicMock name='mock().foo().bar().baz()' id='...'>
>>> m.one().two().three()
<MagicMock name='mock.one().two().three()' id='...'>
>>> calls = call.one().two().three().call_list()
>>> m.assert_has_calls(calls)
```

Even though the chained call `m.one().two().three()` aren't the only calls that have been made to the mock, the assert still succeeds.

Sometimes a mock may have several calls made to it, and you are only interested in asserting about *some* of those calls. You may not even care about the order. In this case you can pass `any_order=True` to `assert_has_calls`:

```
>>> m = MagicMock()
>>> m(1), m.two(2, 3), m.seven(7), m.fifty('50')
(...)
>>> calls = [call.fifty('50'), call(1), call.seven(7)]
>>> m.assert_has_calls(calls, any_order=True)
```

More complex argument matching

Using the same basic concept as **`ANY`** we can implement matchers to do more complex assertions on objects used as arguments to mocks.

Suppose we expect some object to be passed to a mock that by default compares equal based on object identity (which is the Python default for user defined classes). To use **`assert_called_with()`** we would need to pass in the exact same object. If we are only interested in some of the attributes of this object then we can create a matcher that will check these attributes for us.

You can see in this example how a 'standard' call to `assert_called_with` isn't sufficient:

```
>>> class Foo:
...     def __init__(self, a, b):
...         self.a, self.b = a, b
...
>>> mock = Mock(return_value=None)
>>> mock(Foo(1, 2))
>>> mock.assert_called_with(Foo(1, 2))
Traceback (most recent call last):
```

```
    ...
AssertionError: Expected: call(<__main__.Foo object at 0
Actual call: call(<__main__.Foo object at 0x...>)
```

A comparison function for our `Foo` class might look something like this:

```
>>> def compare(self, other):
...     if not type(self) == type(other):
...         return False
...     if self.a != other.a:
...         return False
...     if self.b != other.b:
...         return False
...     return True
...
```

And a matcher object that can use comparison functions like this for its equality operation would look something like this:

```
>>> class Matcher:
...     def __init__(self, compare, some_obj):
...         self.compare = compare
...         self.some_obj = some_obj
...     def __eq__(self, other):
...         return self.compare(self.some_obj, other)
...
```

Putting all this together:

```
>>> match_foo = Matcher(compare, Foo(1, 2))
>>> mock.assert_called_with(match_foo)
```

The `Matcher` is instantiated with our compare function and the `Foo` object we want to compare against. In `assert_called_with` the `Matcher` equality method will be called, which compares the object the mock was called with against the one we created our matcher with. If they match then `assert_called_with` passes, and if they don't an **`AssertionError`** is raised:

```
>>> match_wrong = Matcher(compare, Foo(3, 4))
>>> mock.assert_called_with(match_wrong)
Traceback (most recent call last):
    ...
AssertionError: Expected: ((<Matcher object at 0x...>,),
Called with: ((<Foo object at 0x...>,), {})
```

With a bit of tweaking you could have the comparison function raise the **`AssertionError`** directly and provide a more useful failure message.

As of version 1.5, the Python testing library PyHamcrest [https://pyhamcrest.readthedocs.io/] provides similar functionality, that may be useful here, in the form of its equality matcher (hamcrest.library.integration.match_equality [https://pyhamcrest.readthedocs.io/en/release-1.8/integration/#module-hamcrest.library.integration.match_equality]).

2to3 — Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of *fixers* to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library **lib2to3** is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3.

Deprecated since version 3.11, will be removed in version 3.13: The `lib2to3` module was marked pending for deprecation in Python 3.9 (raising **PendingDeprecationWarning** on import) and fully deprecated in Python 3.11 (raising **DeprecationWarning**). The `2to3` tool is part of that. It will be removed in Python 3.13.

Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3's basic arguments are a list of files or directories to transform. The directories are recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```
def greet(name):
    print "Hello, {0}!".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless **`-n`** is also given.) Writing the changes back is enabled with the **`-w`** flag:

```
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```
def greet(name):
    print("Hello, {0}!".format(name))
print("What's your name?")
name = input()
greet(name)
```

Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of predefined fixers. The **`-l`** flag lists all available fixers. An explicit set of fixers to run can be given with **`-f`**. Likewise the **`-x`** explicitly disables a fixer. The following example runs only the `imports` and `has_key` fixers:

```
$ 2to3 -f imports -f has_key example.py
```

This command runs every fixer except the `apply` fixer:

```
$ 2to3 -x apply example.py
```

Some fixers are *explicit*, meaning they aren't run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the `idioms` fixer is run:

```
$ 2to3 -f all -f idioms example.py
```

Notice how passing `all` enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address

the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the **-d** flag. Note that *only* doctests will be refactored. This also doesn't require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.

The **-v** option enables output of more information on the translation process.

Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the `from __future__ import print_function` compiler directive, it modifies its internal grammar to interpret **`print()`** as a function. This change can also be enabled manually with the **-p** flag. Use **-p** to run fixers on code that already has had its print statements converted. Also **-e** can be used to make **`exec()`** a function.

The **-o** or **--output-dir** option allows specification of an alternate directory for processed output files to be written to. The **-n** flag is required when using this as backup files do not make sense when not overwriting the input files.

New in version 3.2.3: The **-o** option was added.

The **-W** or **--write-unchanged-files** flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with **-o** so that an entire Python source tree is copied with translation from one directory to another. This option implies the **-w** flag as it would not make sense otherwise.

New in version 3.2.3: The **-W** flag was added.

The **--add-suffix** option specifies a string to append to all output filenames. The **-n** flag is required when specifying this as backups are not necessary when writing to different filenames. Example:

```
$ 2to3 -n -W --add-suffix=3 example.py
```

Will cause a converted file named `example.py3` to be written.

New in version 3.2.3: The **`--add-suffix`** option was added.

To translate an entire project from one directory tree to another use:

```
$ 2to3 --output-dir=python3-version/mycode -W -n python2
```

Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As documented above, each can be turned on and off individually. They are described here in more detail.

apply

Removes usage of **`apply()`**. For example `apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs)`.

asserts

Replaces deprecated **`unittest`** method names with the correct ones.

From	To
`failUnlessEqual(a, b)`	`assertEqual(a, b)`
`assertEquals(a, b)`	`assertEqual(a, b)`
`failIfEqual(a, b)`	`assertNotEqual(a, b)`
`assertNotEquals(a, b)`	`assertNotEqual(a, b)`
`failUnless(a)`	`assertTrue(a)`
`assert_(a)`	`assertTrue(a)`
`failIf(a)`	`assertFalse(a)`
`failUnlessRaises(exc, cal)`	`assertRaises(exc, cal)`
`failUnlessAlmostEqual(a, b)`	`assertAlmostEqual(a, b)`
`assertAlmostEquals(a, b)`	`assertAlmostEqual(a, b)`
`failIfAlmostEqual(a, b)`	`assertNotAlmostEqual(a, b)`
`assertNotAlmostEquals(a, b)`	`assertNotAlmostEqual(a, b)`

basestring

Converts **basestring** to **str**.

buffer

Converts **buffer** to **memoryview**. This fixer is optional because the **memoryview** API is similar but not exactly the same as that of **buffer**.

dict

Fixes dictionary iteration methods. **dict.iteritems()** is converted to **dict.items()**, **dict.iterkeys()** to **dict.keys()**, and **dict.itervalues()** to **dict.values()**. Similarly, **dict.viewitems()**, **dict.viewkeys()** and **dict.viewvalues()** are converted respectively to **dict.items()**, **dict.keys()** and **dict.values()**. It also wraps existing usages of **dict.items()**, **dict.keys()**, and **dict.values()** in a call to **list**.

except

Converts `except X, T` to `except X as T`.

exec

Converts the `exec` statement to the **exec()** function.

execfile

Removes usage of **execfile()**. The argument to **execfile()** is wrapped in calls to **open()**, **compile()**, and **exec()**.

exitfunc

Changes assignment of **sys.exitfunc** to use of the **atexit** module.

filter

Wraps **filter()** usage in a **list** call.

funcattrs

Fixes function attributes that have been renamed. For example, `my_function.func_closure` is converted to `my_function.__closure__`.

future

Removes `from __future__ import new_feature` statements.

getcwdu

Renames **`os.getcwdu()`** to **`os.getcwd()`**.

has_key

Changes `dict.has_key(key)` to `key in dict`.

idioms

This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like `type(x) is SomeClass` and `type(x) == SomeClass` are converted to `isinstance(x, SomeClass)`. `while 1` becomes `while True`. This fixer also tries to make use of **`sorted()`** in appropriate places. For example, this block

```
L = list(some_iterable)
L.sort()
```

is changed to

```
L = sorted(some_iterable)
```

import

Detects sibling imports and converts them to relative imports.

imports

Handles module renames in the standard library.

imports2

Handles other modules renames in the standard library. It is

separate from the **imports** fixer only because of technical limitations.

input

Converts `input(prompt)` to `eval(input(prompt))`.

intern

Converts **intern()** to **sys.intern()**.

isinstance

Fixes duplicate types in the second argument of **isinstance()**. For example, `isinstance(x, (int, int))` is converted to `isinstance(x, int)` and `isinstance(x, (int, float, int))` is converted to `isinstance(x, (int, float))`.

itertools_imports

Removes imports of **itertools.ifilter()**, **itertools.izip()**, and **itertools.imap()**. Imports of **itertools.ifilterfalse()** are also changed to **itertools.filterfalse()**.

itertools

Changes usage of **itertools.ifilter()**, **itertools.izip()**, and **itertools.imap()** to their built-in equivalents. **itertools.ifilterfalse()** is changed to **itertools.filterfalse()**.

long

Renames **long** to **int**.

map

Wraps **map()** in a **list** call. It also changes `map(None, x)` to `list(x)`. Using `from future_builtins import map` disables this fixer.

metaclass

Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new (`class X(metaclass=Meta)`).

methodattrs

Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

ne

Converts the old not-equal syntax, `<>`, to `!=`.

next

Converts the use of iterator's **`next()`** methods to the **`next()`** function. It also renames **`next()`** methods to **`__next__()`**.

nonzero

Renames definitions of methods called **`__nonzero__()`** to **`__bool__()`**.

numliterals

Converts octal literals into the new syntax.

operator

Converts calls to various functions in the **`operator`** module to other, but equivalent, function calls. When needed, the appropriate `import` statements are added, e.g. `import collections.abc`. The following mapping are made:

From	To
operator.isCallable(obj)	callable(obj)
operator.sequenceIncludes(obj)	operator.contains(obj)
operator.isSequenceType(obj)	isinstance(obj, collections.abc.Sequence)
operator.isMappingType(obj)	isinstance(obj, collections.abc.Mapping)
operator.isNumberType(obj)	isinstance(obj, numbers.Number)
operator.repeat(obj, n)	operator.mul(obj, n)
operator.irepeat(obj, n)	operator.imul(obj, n)

paren

Add extra parenthesis where they are required in list comprehensions. For example, `[x for x in 1, 2]` becomes `[x for x in (1, 2)]`.

print

Converts the `print` statement to the **`print()`** function.

raise

Converts `raise E, V` to `raise E(V)`, and `raise E, V, T` to `raise E(V).with_traceback(T)`. If `E` is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in 3.0.

raw_input

Converts **`raw_input()`** to **`input()`**.

reduce

Handles the move of **`reduce()`** to **`functools.reduce()`**.

reload

Converts **`reload()`** to **`importlib.reload()`**.

renames

Changes **`sys.maxint`** to **`sys.maxsize`**.

repr

Replaces backtick repr with the **`repr()`** function.

set_literal

Replaces use of the **`set`** constructor with set literals. This fixer is optional.

standarderror

Renames **`StandardError`** to **`Exception`**.

sys_exc

Changes the deprecated **`sys.exc_value`**, **`sys.exc_type`**, **`sys.exc_traceback`** to use **`sys.exc_info()`**.

throw

Fixes the API change in generator's **`throw()`** method.

tuple_params

Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

types

Fixes code broken from the removal of some members in the **`types`** module.

unicode

Renames **`unicode`** to **`str`**.

urllib

Handles the rename of **`urllib`** and **`urllib2`** to the **`urllib`** package.

ws_comma

Removes excess whitespace from comma separated items. This fixer is optional.

xrange

Renames **`xrange()`** to **`range()`** and wraps existing **`range()`** calls with **`list`**.

xreadlines

Changes `for x in file.xreadlines()` to `for x in file`.

zip

Wraps **`zip()`** usage in a **`list`** call. This is disabled when

`from future_builtins import zip` appears.

`lib2to3` — 2to3's library

Source code: Lib/lib2to3/ [https://github.com/python/cpython/tree/3.11/Lib/lib2to3/]

Deprecated since version 3.11, will be removed in version 3.13: Python 3.9 switched to a PEG parser (see **PEP 617** [https://peps.python.org/pep-0617/]) while lib2to3 is using a less flexible LL(1) parser. Python 3.10 includes new language syntax that is not parsable by lib2to3's LL(1) parser (see **PEP 634** [https://peps.python.org/pep-0634/]). The `lib2to3` module was marked pending for deprecation in Python 3.9 (raising **`PendingDeprecationWarning`** on import) and fully deprecated in Python 3.11 (raising **`DeprecationWarning`**). It will be removed from the standard library in Python 3.13. Consider third-party alternatives such as LibCST [https://libcst.readthedocs.io/] or parso [https://parso.readthedocs.io/].

Note

The **`lib2to3`** API should be considered unstable and may change drastically in the future.

`test` — Regression tests package for Python

Note

The `test` package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python's standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

The `test` package contains all regression tests for Python as well as the modules `test.support` and `test.regrtest`. `test.support` is used to enhance your tests while `test.regrtest` drives the testing suite.

Each module in the `test` package whose name starts with `test_` is a testing suite for a specific module or feature. All new tests should be written using the `unittest` or `doctest` module. Some older tests are written using a "traditional" testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

See also

Module `unittest`
Writing PyUnit regression tests.

Module `doctest`
Tests embedded in documentation strings.

Writing Unit Tests for the `test` package

It is preferred that tests that use the **unittest** module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```
import unittest
from test import support

class MyTestCase1(unittest.TestCase):

    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests ...

    def tearDown(self):
        ... code to execute to clean up after tests ...

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...

    def test_feature_two(self):
        # Test feature two.
        ... testing code ...

    ... more test methods ...

class MyTestCase2(unittest.TestCase):
    ... same structure as MyTestCase1 ...
```

```
... more test classes ...

if __name__ == '__main__':
    unittest.main()
```

This code pattern allows the testing suite to be run by **`test.regrtest`**, on its own as a script that supports the **`unittest`** CLI, or via the `python -m unittest` CLI.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.
- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.
- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.
- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.
- Make sure to clean up after your tests (such as close and remove all temporary files).
- If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

- Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.

- Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

  ```
  class TestFuncAcceptsSequencesMixin:

      func = mySuperWhammyFunction

      def test_func(self):
          self.func(self.arg)

  class AcceptLists(TestFuncAcceptsSequencesMixin, un
      arg = [1, 2, 3]

  class AcceptStrings(TestFuncAcceptsSequencesMixin,
      arg = 'abc'

  class AcceptTuples(TestFuncAcceptsSequencesMixin, u
      arg = (1, 2, 3)
  ```

  When using this pattern, remember that all classes that inherit from **unittest.TestCase** are run as tests. The **Mixin** class in the example above does not have any data and so can't be run by itself, thus it does not inherit from **unittest.TestCase**.

See also

Test Driven Development
A book by Kent Beck on writing tests before code.

Running tests using the command-line

interface

The `test` package can be run as a script to drive Python's regression test suite, thanks to the `-m` option: **python -m test**. Under the hood, it uses `test.regrtest`; the call **python -m test.regrtest** used in previous Python versions still works. Running the script by itself automatically starts running all regression tests in the `test` package. It does this by finding all modules in the package whose name starts with `test_`, importing them, and executing the function `test_main()` if present or loading the tests via unittest.TestLoader.loadTestsFromModule if `test_main` does not exist. The names of tests to execute may also be passed to the script. Specifying a single regression test (**python -m test test_spam**) will minimize output and only print whether the test passed or failed.

Running `test` directly allows what resources are available for tests to use to be set. You do this by using the `-u` command-line option. Specifying `all` as the value for the `-u` option enables all possible resources: **python -m test -uall**. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after `all`. The command **python -m test -uall,-audio,-largefile** will run `test` with all resources except the `audio` and `largefile` resources. For a list of all resources and more command-line options, run **python -m test -h**.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run **make test** at the top-level directory where Python was built. On Windows, executing **rt.bat** from your `PCbuild` directory will run all regression tests.

`test.support` — Utilities for the Python test suite

The `test.support` module provides support for Python's

regression test suite.

Note

test.support is not a public module. It is documented here to help Python developers write tests. The API of this module is subject to change without backwards compatibility concerns between releases.

This module defines the following exceptions:

exception test.support.TestFailed

Exception to be raised when a test fails. This is deprecated in favor of **unittest**-based tests and **unittest.TestCase**'s assertion methods.

exception test.support.ResourceDenied

Subclass of **unittest.SkipTest**. Raised when a resource (such as a network connection) is not available. Raised by the **requires()** function.

The **test.support** module defines the following constants:

test.support.verbose

`True` when verbose output is enabled. Should be checked when more detailed information is desired about a running test. *verbose* is set by **test.regrtest**.

test.support.is_jython

`True` if the running interpreter is Jython.

test.support.is_android

`True` if the system is Android.

test.support.unix_shell

Path for shell if not on Windows; otherwise `None`.

test.support.LOOPBACK_TIMEOUT

Timeout in seconds for tests using a network server listening on the network local loopback interface like `127.0.0.1`.

The timeout is long enough to prevent test failure: it takes into account that the client and the server can run in different threads or even different processes.

The timeout should be long enough for **`connect()`**, **`recv()`** and **`send()`** methods of **`socket.socket`**.

Its default value is 5 seconds.

See also **`INTERNET_TIMEOUT`**.

test.support.INTERNET_TIMEOUT

Timeout in seconds for network requests going to the internet.

The timeout is short enough to prevent a test to wait for too long if the internet request is blocked for whatever reason.

Usually, a timeout using **`INTERNET_TIMEOUT`** should not mark a test as failed, but skip the test instead: see **`transient_internet()`**.

Its default value is 1 minute.

See also **`LOOPBACK_TIMEOUT`**.

test.support.SHORT_TIMEOUT

Timeout in seconds to mark a test as failed if the test takes “too long”.

The timeout value depends on the regrtest `--timeout` command line option.

If a test using **`SHORT_TIMEOUT`** starts to fail randomly on slow buildbots, use **`LONG_TIMEOUT`** instead.

Its default value is 30 seconds.

test.support.LONG_TIMEOUT

Timeout in seconds to detect when a test hangs.

It is long enough to reduce the risk of test failure on the slowest Python buildbots. It should not be used to mark a test as failed if the test takes "too long". The timeout value depends on the regrtest `--timeout` command line option.

Its default value is 5 minutes.

See also **`LOOPBACK_TIMEOUT`**, **`INTERNET_TIMEOUT`** and **`SHORT_TIMEOUT`**.

test.support.PGO

Set when tests can be skipped when they are not useful for PGO.

test.support.PIPE_MAX_SIZE

A constant that is likely larger than the underlying OS pipe buffer size, to make writes blocking.

test.support.SOCK_MAX_SIZE

A constant that is likely larger than the underlying OS socket buffer size, to make writes blocking.

test.support.TEST_SUPPORT_DIR

Set to the top level directory that contains **`test.support`**.

test.support.TEST_HOME_DIR

Set to the top level directory for the test package.

test.support.TEST_DATA_DIR

Set to the `data` directory within the test package.

test.support.MAX_Py_ssize_t

Set to **`sys.maxsize`** for big memory tests.

test.support.max_memuse

Set by **set_memlimit()** as the memory limit for big memory tests. Limited by **MAX_Py_ssize_t**.

test.support.real_max_memuse

Set by **set_memlimit()** as the memory limit for big memory tests. Not limited by **MAX_Py_ssize_t**.

test.support.MISSING_C_DOCSTRINGS

Set to `True` if Python is built without docstrings (the **WITH_DOC_STRINGS** macro is not defined). See the **configure --without-doc-strings** option.

See also the **HAVE_DOCSTRINGS** variable.

test.support.HAVE_DOCSTRINGS

Set to `True` if function docstrings are available. See the **python -OO** option, which strips docstrings of functions implemented in Python.

See also the **MISSING_C_DOCSTRINGS** variable.

test.support.TEST_HTTP_URL

Define the URL of a dedicated HTTP server for the network tests.

test.support.ALWAYS_EQ

Object that is equal to anything. Used to test mixed type comparison.

test.support.NEVER_EQ

Object that is not equal to anything (even to **ALWAYS_EQ**). Used to test mixed type comparison.

test.support.LARGEST

Object that is greater than anything (except itself). Used to test mixed type comparison.

test.support.SMALLEST

Object that is less than anything (except itself). Used to test mixed type comparison.

The **test.support** module defines the following functions:

test.support.is_resource_enabled(*resource*)

Return `True` if *resource* is enabled and available. The list of available resources is only set when **test.regrtest** is executing the tests.

test.support.python_is_optimized()

Return `True` if Python was not built with `-O0` or `-Og`.

test.support.with_pymalloc()

Return **_testcapi.WITH_PYMALLOC**.

test.support.requires(*resource*, *msg*=*None*)

Raise **ResourceDenied** if *resource* is not available. *msg* is the argument to **ResourceDenied** if it is raised. Always returns `True` if called by a function whose `__name__` is `'__main__'`. Used when tests are executed by **test.regrtest**.

test.support.sortdict(*dict*)

Return a repr of *dict* with keys sorted.

test.support.findfile(*filename*, *subdir*=*None*)

Return the path to the file named *filename*. If no match is found *filename* is returned. This does not equal a failure since it could be the path to the file.

Setting *subdir* indicates a relative path to use to find the file rather than looking directly in the path directories.

test.support.match_test(*test*)

Determine whether *test* matches the patterns set in

set_match_tests().

test.support.set_match_tests(*accept_patterns* = *None*, *ignore_patterns* = *None*)

Define match patterns on test filenames and test method names for filtering tests.

test.support.run_unittest(**classes*)

Execute **unittest.TestCase** subclasses passed to the function. The function scans the classes for methods starting with the prefix `test_` and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in `sys.modules`. Each associated module will be scanned by `unittest.TestLoader.loadTestsFromModule()`. This is usually seen in the following **test_main()** function:

```
def test_main():
    support.run_unittest(__name__)
```

This will run all tests defined in the named module.

test.support.run_doctest(*module*, *verbosity* = *None*, *optionflags* = *0*)

Run **doctest.testmod()** on the given *module*. Return `(failure_count, test_count)`.

If *verbosity* is `None`, **doctest.testmod()** is run with verbosity set to **verbose**. Otherwise, it is run with verbosity set to `None`. *optionflags* is passed as `optionflags` to **doctest.testmod()**.

test.support.setswitchinterval(*interval*)

Set the **sys.setswitchinterval()** to the given *interval*. Defines a minimum interval for Android systems to prevent the system from hanging.

test.support.check_impl_detail(***guards*)

Use this check to guard CPython's implementation-specific tests or to run them only on the implementations guarded by the arguments. This function returns `True` or `False` depending on the host platform. Example usage:

```
check_impl_detail()               # Only on CPython
check_impl_detail(jython=True)    # Only on Jython.
check_impl_detail(cpython=False)  # Everywhere exce
```

test.support.set_memlimit(*limit*)

Set the values for **`max_memuse`** and **`real_max_memuse`** for big memory tests.

test.support.record_original_stdout(*stdout*)

Store the value from *stdout*. It is meant to hold the stdout at the time the regrtest began.

test.support.get_original_stdout()

Return the original stdout set by **`record_original_stdout()`** or `sys.stdout` if it's not set.

test.support.args_from_interpreter_flags()

Return a list of command line arguments reproducing the current settings in `sys.flags` and `sys.warnoptions`.

test.support.optim_args_from_interpreter_flags()

Return a list of command line arguments reproducing the current optimization settings in `sys.flags`.

test.support.captured_stdin()

test.support.captured_stdout()

test.support.captured_stderr()

A context managers that temporarily replaces the named stream with **`io.StringIO`** object.

Example use with output streams:

```
with captured_stdout() as stdout, captured_stderr()
    print("hello")
    print("error", file=sys.stderr)
assert stdout.getvalue() == "hello\n"
assert stderr.getvalue() == "error\n"
```

Example use with input stream:

```
with captured_stdin() as stdin:
    stdin.write('hello\n')
    stdin.seek(0)
    # call test code that consumes from sys.stdin
    captured = input()
self.assertEqual(captured, "hello")
```

test.support.disable_faulthandler()

A context manager that temporary disables **faulthandler**.

test.support.gc_collect()

Force as many objects as possible to be collected. This is needed because timely deallocation is not guaranteed by the garbage collector. This means that `__del__` methods may be called later than expected and weakrefs may remain alive for longer than expected.

test.support.disable_gc()

A context manager that disables the garbage collector on entry. On exit, the garbage collector is restored to its prior state.

test.support.swap_attr(*obj*, *attr*, *new_val*)

Context manager to swap out an attribute with a new object.

Usage:

```
with swap_attr(obj, "attr", 5):
```

```
    ...
```

This will set `obj.attr` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `attr` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

test.support.swap_item(*obj*, *attr*, *new_val*)

Context manager to swap out an item with a new object.

Usage:

```
with swap_item(obj, "item", 5):
    ...
```

This will set `obj["item"]` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `item` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

test.support.flush_std_streams()

Call the `flush()` method on **`sys.stdout`** and then on **`sys.stderr`**. It can be used to make sure that the logs order is consistent before writing into stderr.

New in version 3.11.

test.support.print_warning(*msg*)

Print a warning into **`sys.__stderr__`**. Format the message as: `f"Warning -- {msg}"`. If *msg* is made of multiple lines, add `"Warning -- "` prefix to each line.

New in version 3.9.

test.support.wait_process(*pid*, *, *exitcode*, *timeout*=*None*)

Wait until process *pid* completes and check that the process exit code is *exitcode*.

Raise an **AssertionError** if the process exit code is not equal to *exitcode*.

If the process runs longer than *timeout* seconds (**SHORT_TIMEOUT** by default), kill the process and raise an **AssertionError**. The timeout feature is not available on Windows.

New in version 3.9.

test.support.calcobjsize(*fmt*)

Return the size of the **PyObject** whose structure members are defined by *fmt*. The returned value includes the size of the Python object header and alignment.

test.support.calcvobjsize(*fmt*)

Return the size of the **PyVarObject** whose structure members are defined by *fmt*. The returned value includes the size of the Python object header and alignment.

test.support.checksizeof(*test*, *o*, *size*)

For testcase *test*, assert that the `sys.getsizeof` for *o* plus the GC header size equals *size*.

@test.support.anticipate_failure(*condition*)

A decorator to conditionally mark tests with **unittest.expectedFailure()**. Any use of this decorator should have an associated comment identifying the relevant tracker issue.

test.support.system_must_validate_cert(*f*)

A decorator that skips the decorated test on TLS certification validation failures.

@test.support.run_with_locale(*catstr*, **locales*)

A decorator for running a function in a different locale, correctly resetting it after it has finished. *catstr* is the locale category as a string (for example `"LC_ALL"`). The *locales* passed will be tried sequentially, and the first valid locale will be used.

@test.support.run_with_tz(*tz*)

A decorator for running a function in a specific timezone, correctly resetting it after it has finished.

@test.support.requires_freebsd_version(**min_version*)

Decorator for the minimum version when running test on FreeBSD. If the FreeBSD version is less than the minimum, the test is skipped.

@test.support.requires_linux_version(**min_version*)

Decorator for the minimum version when running test on Linux. If the Linux version is less than the minimum, the test is skipped.

@test.support.requires_mac_version(**min_version*)

Decorator for the minimum version when running test on macOS. If the macOS version is less than the minimum, the test is skipped.

@test.support.requires_IEEE_754

Decorator for skipping tests on non-IEEE 754 platforms.

@test.support.requires_zlib

Decorator for skipping tests if **`zlib`** doesn't exist.

@test.support.requires_gzip

Decorator for skipping tests if **`gzip`** doesn't exist.

@test.support.requires_bz2

Decorator for skipping tests if **bz2** doesn't exist.

@test.support.requires_lzma

Decorator for skipping tests if **lzma** doesn't exist.

@test.support.requires_resource(*resource*)

Decorator for skipping tests if *resource* is not available.

@test.support.requires_docstrings

Decorator for only running the test if **HAVE_DOCSTRINGS**.

@test.support.cpython_only

Decorator for tests only applicable to CPython.

@test.support.impl_detail(*msg=None*, ***guards*)

Decorator for invoking **check_impl_detail()** on *guards*. If that returns `False`, then uses *msg* as the reason for skipping the test.

@test.support.no_tracing

Decorator to temporarily turn off tracing for the duration of the test.

@test.support.refcount_test

Decorator for tests which involve reference counting. The decorator does not run the test if it is not run by CPython. Any trace function is unset for the duration of the test to prevent unexpected refcounts caused by the trace function.

@test.support.bigmemtest(*size*, *memuse*, *dry_run=True*)

Decorator for bigmem tests.

size is a requested size for the test (in arbitrary, test-interpreted units.) *memuse* is the number of bytes per unit for the test, or a good estimate of it. For example, a test that needs two byte buffers, of 4 GiB each, could be decorated with `@bigmemtest(size=_4G, memuse=2)`.

The *size* argument is normally passed to the decorated test method as an extra argument. If *dry_run* is `True`, the value passed to the test method may be less than the requested value. If *dry_run* is `False`, it means the test doesn't support dummy runs when `-M` is not specified.

@test.support.bigaddrspacetest

Decorator for tests that fill the address space.

test.support.check_syntax_error(*testcase*, *statement*, *errtext*='', *, *lineno*=*None*, *offset*=*None*)

Test for syntax errors in *statement* by attempting to compile *statement*. *testcase* is the **unittest** instance for the test. *errtext* is the regular expression which should match the string representation of the raised **SyntaxError**. If *lineno* is not `None`, compares to the line of the exception. If *offset* is not `None`, compares to the offset of the exception.

test.support.open_urlresource(*url*, **args*, ***kw*)

Open *url*. If open fails, raises **TestFailed**.

test.support.reap_children()

Use this at the end of `test_main` whenever sub-processes are started. This will help ensure that no extra children (zombies) stick around to hog resources and create problems when looking for refleaks.

test.support.get_attribute(*obj*, *name*)

Get an attribute, raising **unittest.SkipTest** if **AttributeError** is raised.

test.support.catch_unraisable_exception()

Context manager catching unraisable exception using **sys.unraisablehook()**.

Storing the exception value (`cm.unraisable.exc_value`) creates a reference cycle. The reference cycle is broken

explicitly when the context manager exits.

Storing the object (`cm.unraisable.object`) can resurrect it if it is set to an object which is being finalized. Exiting the context manager clears the stored object.

Usage:

```
with support.catch_unraisable_exception() as cm:
    # code creating an "unraisable exception"
    ...

    # check the unraisable exception: use cm.unrais
    ...

# cm.unraisable attribute no longer exists at this
# (to break a reference cycle)
```

New in version 3.8.

test.support.load_package_tests(*pkg_dir*, *loader*, *standard_tests*, *pattern*)

Generic implementation of the **unittest** `load_tests` protocol for use in test packages. *pkg_dir* is the root directory of the package; *loader*, *standard_tests*, and *pattern* are the arguments expected by `load_tests`. In simple cases, the test package's `__init__.py` can be the following:

```
import os
from test.support import load_package_tests

def load_tests(*args):
    return load_package_tests(os.path.dirname(__fil
```

test.support.detect_api_mismatch(*ref_api*, *other_api*, *, *ignore=()*)

Returns the set of attributes, functions or methods of *ref_api* not found on *other_api*, except for a defined list of items to be ignored in this check specified in *ignore*.

By default this skips private attributes beginning with '_' but includes all magic methods, i.e. those starting and ending in '__'.

New in version 3.5.

test.support.patch(*test_instance*, *object_to_patch*, *attr_name*, *new_value*)

Override *object_to_patch.attr_name* with *new_value*. Also add cleanup procedure to *test_instance* to restore *object_to_patch* for *attr_name*. The *attr_name* should be a valid attribute for *object_to_patch*.

test.support.run_in_subinterp(*code*)

Run *code* in subinterpreter. Raise **unittest.SkipTest** if **tracemalloc** is enabled.

test.support.check_free_after_iterating(*test*, *iter*, *cls*, *args=()*)

Assert instances of *cls* are deallocated after iterating.

test.support.missing_compiler_executable(*cmd_names=[]*)

Check for the existence of the compiler executables whose names are listed in *cmd_names* or all the compiler executables when *cmd_names* is empty and return the first missing executable or `None` when none is found missing.

test.support.check__all__(*test_case*, *module*, *name_of_module=None*, *extra=()*, *not_exported=()*)

Assert that the `__all__` variable of *module* contains all public names.

The module's public names (its API) are detected automatically based on whether they match the public name convention and were defined in *module*.

The *name_of_module* argument can specify (as a string or tuple thereof) what module(s) an API could be defined in order to be detected as a public API. One case for this is when *module*

imports part of its public API from other modules, possibly a C backend (like `csv` and its `_csv`).

The *extra* argument can be a set of names that wouldn't otherwise be automatically detected as "public", like objects without a proper `__module__` attribute. If provided, it will be added to the automatically detected ones.

The *not_exported* argument can be a set of names that must not be treated as part of the public API even though their names indicate otherwise.

Example use:

```
import bar
import foo
import unittest
from test import support

class MiscTestCase(unittest.TestCase):
    def test__all__(self):
        support.check__all__(self, foo)

class OtherTestCase(unittest.TestCase):
    def test__all__(self):
        extra = {'BAR_CONST', 'FOO_CONST'}
        not_exported = {'baz'}  # Undocumented name
        # bar imports part of its API from _bar.
        support.check__all__(self, bar, ('bar', '_b
                             extra=extra, not_expor
```

New in version 3.6.

test.support.skip_if_broken_multiprocessing_synchronize()

Skip tests if the **`multiprocessing.synchronize`** module is missing, if there is no available semaphore implementation, or if creating a lock raises an **`OSError`**.

New in version 3.10.

test.support.check_disallow_instantiation(*test_case*, *tp*, **args*, ***kwds*)

Assert that type *tp* cannot be instantiated using *args* and *kwds*.

New in version 3.10.

test.support.adjust_int_max_str_digits(*max_digits*)

This function returns a context manager that will change the global **sys.set_int_max_str_digits()** setting for the duration of the context to allow execution of test code that needs a different limit on the number of digits when converting between an integer and string.

New in version 3.11.

The **test.support** module defines the following classes:

class test.support.SuppressCrashReport

A context manager used to try to prevent crash dialog popups on tests that are expected to crash a subprocess.

On Windows, it disables Windows Error Reporting dialogs using SetErrorMode [https://msdn.microsoft.com/en-us/library/windows/desktop/ms680621.aspx].

On UNIX, **resource.setrlimit()** is used to set **resource.RLIMIT_CORE**'s soft limit to 0 to prevent coredump file creation.

On both platforms, the old value is restored by **__exit__()**.

class test.support.SaveSignals

Class to save and restore signal handlers registered by the Python signal handler.

save(*self*)

Save the signal handlers to a dictionary mapping signal numbers to the current signal handler.

restore(*self*)

Set the signal numbers from the `save()` dictionary to the saved handler.

class test.support.Matcher

matches(*self*, *d*, ***kwargs*)

Try to match a single dict with the supplied arguments.

match_value(*self*, *k*, *dv*, *v*)

Try to match a single stored value (*dv*) with a supplied value (*v*).

class test.support.BasicTestRunner

run(*test*)

Run *test* and return the result.

`test.support.socket_helper` — Utilities for socket tests

The `test.support.socket_helper` module provides support for socket tests.

New in version 3.9.

test.support.socket_helper.IPV6_ENABLED

Set to `True` if IPv6 is enabled on this host, `False` otherwise.

test.support.socket_helper.find_unused_port(*family=socket.AF_INET*, *socktype=socket.SOCK_STREAM*)

Returns an unused port that should be suitable for binding. This is achieved by creating a temporary socket with the same family and type as the `sock` parameter (default is

AF_INET, **SOCK_STREAM**), and binding it to the specified host address (defaults to `0.0.0.0`) with the port set to 0, eliciting an unused ephemeral port from the OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or **bind_port()** should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a Python socket, or if an unused port needs to be provided in a constructor or passed to an external program (i.e. the `-accept` argument to openssl's s_server mode). Always prefer **bind_port()** over **find_unused_port()** where possible. Using a hard coded port is discouraged since it can make multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

test.support.socket_helper.bind_port(*sock*, *host=HOST*)

Bind the socket to a free port and return the port number. Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the `sock.family` is **AF_INET** and `sock.type` is **SOCK_STREAM**, and the socket has **SO_REUSEADDR** or **SO_REUSEPORT** set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the **SO_EXCLUSIVEADDRUSE** socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

test.support.socket_helper.bind_unix_socket(*sock*, *addr*)

Bind a Unix socket, raising **unittest.SkipTest** if **PermissionError** is raised.

@test.support.socket_helper.skip_unless_bind_unix_socket

A decorator for running tests that require a functional `bind()` for Unix sockets.

test.support.socket_helper.transient_internet(*resource_name*, *, *timeout=30.0*, *errnos=()*)

A context manager that raises **ResourceDenied** when various issues with the internet connection manifest themselves as exceptions.

test.support.script_helper — Utilities for the Python execution tests

The **test.support.script_helper** module provides support for Python's script execution tests.

test.support.script_helper.interpreter_requires_environment()

Return `True` if `sys.executable` `interpreter` requires environment variables in order to be able to run at all.

This is designed to be used with `@unittest.skipIf()` to annotate tests that need to use an `assert_python*()` function to launch an isolated mode (`-I`) or no environment mode (`-E`) sub-interpreter process.

A normal build & test does not run into this situation but it can happen when trying to run the standard library test suite from an interpreter that doesn't have an obvious home with Python's current home finding logic.

Setting **PYTHONHOME** is one way to get most of the testsuite to run in that situation. **PYTHONPATH** or **PYTHONUSERSITE** are other common environment variables that might impact

whether or not the interpreter can start.

test.support.script_helper.run_python_until_end(**args*, ***env_vars*)

Set up the environment based on *env_vars* for running the interpreter in a subprocess. The values can include `__isolated`, `__cleanenv`, `__cwd`, and `TERM`.

Changed in version 3.9: The function no longer strips whitespaces from *stderr*.

test.support.script_helper.assert_python_ok(**args*, ***env_vars*)

Assert that running the interpreter with *args* and optional environment variables *env_vars* succeeds (`rc == 0`) and return a `(return code, stdout, stderr)` tuple.

If the *_cleanenv* keyword-only parameter is set, *env_vars* is used as a fresh environment.

Python is started in isolated mode (command line option `-I`), except if the *_isolated* keyword-only parameter is set to `False`.

Changed in version 3.9: The function no longer strips whitespaces from *stderr*.

test.support.script_helper.assert_python_failure(**args*, ***env_vars*)

Assert that running the interpreter with *args* and optional environment variables *env_vars* fails (`rc != 0`) and return a `(return code, stdout, stderr)` tuple.

See **`assert_python_ok()`** for more options.

Changed in version 3.9: The function no longer strips whitespaces from *stderr*.

test.support.script_helper.spawn_python(**args*, *stdout=subprocess.PIPE*, *stderr=subprocess.STDOUT*, ***kw*)

Run a Python subprocess with the given arguments.

kw is extra keyword args to pass to **subprocess.Popen()**. Returns a **subprocess.Popen** object.

test.support.script_helper.kill_python(*p*)

Run the given **subprocess.Popen** process until completion and return stdout.

test.support.script_helper.make_script(*script_dir*, *script_basename*, *source*, *omit_suffix=False*)

Create script containing *source* in path *script_dir* and *script_basename*. If *omit_suffix* is `False`, append `.py` to the name. Return the full script path.

test.support.script_helper.make_zip_script(*zip_dir*, *zip_basename*, *script_name*, *name_in_zip=None*)

Create zip file at *zip_dir* and *zip_basename* with extension `zip` which contains the files in *script_name*. *name_in_zip* is the archive name. Return a tuple containing `(full path, full path of archive name)`.

test.support.script_helper.make_pkg(*pkg_dir*, *init_source=''*)

Create a directory named *pkg_dir* containing an `__init__` file with *init_source* as its contents.

test.support.script_helper.make_zip_pkg(*zip_dir*, *zip_basename*, *pkg_name*, *script_basename*, *source*, *depth=1*, *compiled=False*)

Create a zip package directory with a path of *zip_dir* and *zip_basename* containing an empty `__init__` file and a file *script_basename* containing the *source*. If *compiled* is `True`, both source files will be compiled and added to the zip package. Return a tuple of the full zip path and the archive name for the zip file.

test.support.bytecode_helper — Support tools for testing correct bytecode generation

The test.support.bytecode_helper module provides support for testing and inspecting bytecode generation.

New in version 3.9.

The module defines the following class:

class test.support.bytecode_helper.BytecodeTestCase(*unittest.TestCase*)

This class has custom assertion methods for inspecting bytecode.

BytecodeTestCase.get_disassembly_as_string(*co*)

Return the disassembly of *co* as string.

BytecodeTestCase.assertInBytecode(*x*, *opname*, *argval=_UNSPECIFIED*)

Return instr if *opname* is found, otherwise throws AssertionError.

BytecodeTestCase.assertNotInBytecode(*x*, *opname*, *argval=_UNSPECIFIED*)

Throws AssertionError if *opname* is found.

test.support.threading_helper — Utilities for threading tests

The **test.support.threading_helper** module provides support for threading tests.

New in version 3.10.

test.support.threading_helper.join_thread(*thread*, *timeout*=*None*)

Join a *thread* within *timeout*. Raise an **AssertionError** if thread is still alive after *timeout* seconds.

@test.support.threading_helper.reap_threads

Decorator to ensure the threads are cleaned up even if the test fails.

test.support.threading_helper.start_threads(*threads*, *unlock*=*None*)

Context manager to start *threads*, which is a sequence of threads. *unlock* is a function called after the threads are started, even if an exception was raised; an example would be **threading.Event.set()**. `start_threads` will attempt to join the started threads upon exit.

test.support.threading_helper.threading_cleanup(**original_values*)

Cleanup up threads not specified in *original_values*. Designed to emit a warning if a test leaves running threads in the background.

test.support.threading_helper.threading_setup()

Return current thread count and copy of dangling threads.

test.support.threading_helper.wait_threads_exit(*timeout*=*None*)

Context manager to wait until all threads created in the `with` statement exit.

test.support.threading_helper.catch_threading_exception()

Context manager catching **threading.Thread** exception using **threading.excepthook()**.

Attributes set when an exception is caught:

- exc_type
- exc_value
- exc_traceback
- thread

See **threading.excepthook()** documentation.

These attributes are deleted at the context manager exit.

Usage:

```
with threading_helper.catch_threading_exception() a
    # code spawning a thread which raises an except
    ...

    # check the thread exception, use cm attributes
    # exc_type, exc_value, exc_traceback, thread
    ...

# exc_type, exc_value, exc_traceback, thread attrib
# exists at this point
# (to avoid reference cycles)
```

New in version 3.8.

test.support.os_helper — Utilities for os tests

The **test.support.os_helper** module provides support for os tests.

New in version 3.10.

test.support.os_helper.FS_NONASCII

A non-ASCII character encodable by **os.fsencode()**.

test.support.os_helper.SAVEDCWD

Set to **os.getcwd()**.

test.support.os_helper.TESTFN

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

test.support.os_helper.TESTFN_NONASCII

Set to a filename containing the **FS_NONASCII** character, if it exists. This guarantees that if the filename exists, it can be encoded and decoded with the default filesystem encoding. This allows tests that require a non-ASCII filename to be easily skipped on platforms where they can't work.

test.support.os_helper.TESTFN_UNENCODABLE

Set to a filename (str type) that should not be able to be encoded by file system encoding in strict mode. It may be `None` if it's not possible to generate such a filename.

test.support.os_helper.TESTFN_UNDECODABLE

Set to a filename (bytes type) that should not be able to be decoded by file system encoding in strict mode. It may be `None` if it's not possible to generate such a filename.

test.support.os_helper.TESTFN_UNICODE

Set to a non-ASCII name for a temporary file.

class test.support.os_helper.EnvironmentVarGuard

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying `os.environ`. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

Changed in version 3.1: Added dictionary interface.

class test.support.os_helper.FakePath(*path*)

Simple path-like object. It implements the **__fspath__()** method which just returns the *path* argument. If *path* is an exception, it will be raised in **__fspath__()**.

EnvironmentVarGuard.set(*envvar*, *value*)

Temporarily set the environment variable `envvar` to the value of `value`.

EnvironmentVarGuard.unset(*envvar*)

Temporarily unset the environment variable `envvar`.

test.support.os_helper.can_symlink()

Return `True` if the OS supports symbolic links, `False` otherwise.

test.support.os_helper.can_xattr()

Return `True` if the OS supports xattr, `False` otherwise.

test.support.os_helper.change_cwd(*path*, *quiet=False*)

A context manager that temporarily changes the current working directory to *path* and yields the directory.

If *quiet* is `False`, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

test.support.os_helper.create_empty_file(*filename*)

Create an empty file with *filename*. If it already exists, truncate it.

test.support.os_helper.fd_count()

Count the number of open file descriptors.

test.support.os_helper.fs_is_case_insensitive(*directory*)

Return `True` if the file system for *directory* is case-insensitive.

test.support.os_helper.make_bad_fd()

Create an invalid file descriptor by opening and closing a temporary file, and returning its descriptor.

test.support.os_helper.rmdir(*filename*)

Call **`os.rmdir()`** on *filename*. On Windows platforms, this is wrapped with a wait loop that checks for the existence of the file, which is needed due to antivirus programs that can hold files open and prevent deletion.

test.support.os_helper.rmtree(*path*)

Call **`shutil.rmtree()`** on *path* or call **`os.lstat()`** and **`os.rmdir()`** to remove a path and its contents. As with **`rmdir()`**, on Windows platforms this is wrapped with a wait loop that checks for the existence of the files.

@test.support.os_helper.skip_unless_symlink

A decorator for running tests that require support for symbolic links.

@test.support.os_helper.skip_unless_xattr

A decorator for running tests that require support for xattr.

test.support.os_helper.temp_cwd(*name='tempcwd'*, *quiet=False*)

A context manager that temporarily creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name *name* before temporarily changing the current working directory. If *name* is `None`, the temporary directory is created using **`tempfile.mkdtemp()`**.

If *quiet* is `False` and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised

and the original CWD is used.

test.support.os_helper.temp_dir(*path=None*, *quiet=False*)

A context manager that creates a temporary directory at *path* and yields the directory.

If *path* is `None`, the temporary directory is created using **`tempfile.mkdtemp()`**. If *quiet* is `False`, the context manager raises an exception on error. Otherwise, if *path* is specified and cannot be created, only a warning is issued.

test.support.os_helper.temp_umask(*umask*)

A context manager that temporarily sets the process umask.

test.support.os_helper.unlink(*filename*)

Call **`os.unlink()`** on *filename*. As with **`rmdir()`**, on Windows platforms, this is wrapped with a wait loop that checks for the existence of the file.

`test.support.import_helper` — Utilities for import tests

The **`test.support.import_helper`** module provides support for import tests.

New in version 3.10.

test.support.import_helper.forget(*module_name*)

Remove the module named *module_name* from `sys.modules` and delete any byte-compiled files of the module.

test.support.import_helper.import_fresh_module(*name*, *fresh=()*, *blocked=()*, *deprecated=False*)

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike **`reload()`**, the original module is not affected by this operation.

fresh is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

blocked is an iterable of module names that are replaced with `None` in the module cache during the import to ensure that attempts to import them raise **`ImportError`**.

The named module and any modules named in the *fresh* and *blocked* parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`.

This function will raise **`ImportError`** if the named module cannot be imported.

Example use:

```
# Get copies of the warnings module for testing wit
# version being used by the rest of the test suite.
# C implementation, the other is forced to use the
# implementation
py_warnings = import_fresh_module('warnings', block
c_warnings = import_fresh_module('warnings', fresh=
```

New in version 3.1.

test.support.import_helper.import_module(*name*, *deprecated=False*, **, required_on=()*)

This function imports and returns the named module. Unlike a normal import, this function raises **`unittest.SkipTest`**

if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`. If a module is required on a platform but optional for others, set *required_on* to an iterable of platform prefixes which will be compared against **`sys.platform`**.

New in version 3.1.

test.support.import_helper.modules_setup()

Return a copy of **`sys.modules`**.

test.support.import_helper.modules_cleanup(*oldmodules*)

Remove modules except for *oldmodules* and `encodings` in order to preserve internal cache.

test.support.import_helper.unload(*name*)

Delete *name* from `sys.modules`.

test.support.import_helper.make_legacy_pyc(*source*)

Move a **PEP 3147** [https://peps.python.org/pep-3147/]/**PEP 488** [https://peps.python.org/pep-0488/] pyc file to its legacy pyc location and return the file system path to the legacy pyc file. The *source* value is the file system path to the source file. It does not need to exist, however the PEP 3147/488 pyc file must exist.

class test.support.import_helper.CleanImport(**module_names*)

A context manager to force import to return a new module reference. This is useful for testing module-level behaviors, such as the emission of a **`DeprecationWarning`** on import. Example usage:

```
with CleanImport('foo'):
    importlib.import_module('foo')  # New reference
```

class test.support.import_helper.DirsOnSysPath(**paths*)

A context manager to temporarily add directories to `sys.path`.

This makes a copy of `sys.path`, appends any directories given as positional arguments, then reverts `sys.path` to the copied settings when the context ends.

Note that *all* `sys.path` modifications in the body of the context manager, including replacement of the object, will be reverted at the end of the block.

`test.support.warnings_helper` — Utilities for warnings tests

The `test.support.warnings_helper` module provides support for warnings tests.

New in version 3.10.

test.support.warnings_helper.check_no_resource_warning(*testcase*)

Context manager to check that no `ResourceWarning` was raised. You must remove the object which may emit `ResourceWarning` before the end of the context manager.

test.support.warnings_helper.check_syntax_warning(*testcase*, *statement*, *errtext='', *, lineno=1, offset=None*)

Test for syntax warning in *statement* by attempting to compile *statement*. Test also that the `SyntaxWarning` is emitted only once, and that it will be converted to a `SyntaxError` when turned into error. *testcase* is the `unittest` instance for the test. *errtext* is the regular expression which should match the string representation of the emitted `SyntaxWarning` and raised `SyntaxError`. If *lineno* is not `None`, compares to the line of the warning and exception. If *offset* is not `None`,

compares to the offset of the exception.

New in version 3.8.

test.support.warnings_helper.check_warnings(**filters*, *quiet*=*True*)

A convenience wrapper for **warnings.catch_warnings()** that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with **warnings.simplefilter()** set to `always` and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form `("message regexp", WarningCategory)` as positional arguments. If one or more *filters* are provided, or if the optional keyword argument *quiet* is `False`, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set *quiet* to `True`.

If no arguments are specified, it defaults to:

```
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a **WarningRecorder** instance is returned. The underlying warnings list from **catch_warnings()** is available via the recorder object's **warnings** attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return `None`.

The recorder object also has a **reset()** method, which clears the warnings list.

The context manager is designed to be used like this:

```
with check_warnings(("assertion is always true", Sy
                     ("", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, **check_warnings()** would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

Changed in version 3.2: New optional arguments *filters* and *quiet*.

class test.support.warnings_helper.WarningsRecorder

Class used to record warnings for unit tests. See documentation of **check_warnings()** above for more details.

Debugging and Profiling

These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs. Auditing events provide visibility into runtime behaviors that would otherwise require intrusive debugging or patching.

- Audit events table
- **bdb** — Debugger framework
- **faulthandler** — Dump the Python traceback
    - Dumping the traceback
    - Fault handler state
    - Dumping the tracebacks after a timeout
    - Dumping the traceback on a user signal
    - Issue with file descriptors

Audit events table

This table contains all events raised by `sys.audit()` or `PySys_Audit()` calls throughout the CPython runtime and the standard library. These calls were added in 3.8.0 or later (see PEP 578 [https://peps.python.org/pep-0578/]).

See `sys.addaudithook()` and `PySys_AddAuditHook()` for information on handling these events.

CPython implementation detail: This table is generated from the CPython documentation, and may not represent events raised by other implementations. See your runtime specific documentation for actual events raised.

bdb — Debugger framework

Source code: Lib/bdb.py [https://github.com/python/cpython/tree/3.11/Lib/bdb.py]

The bdb module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

exception bdb.BdbQuit

Exception raised by the Bdb class for quitting the debugger.

The bdb module also defines two classes:

class bdb.Breakpoint(*self*, *file*, *line*, *temporary=False*, *cond=None*, *funcname=None*)

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called bpbynumber and by `(file, line)` pairs through bplist. The former points to a single instance of class Breakpoint. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated file name should be in canonical form. If a funcname is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

Breakpoint instances have the following methods:

deleteMe()

Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

enable()

Mark the breakpoint as enabled.

disable()

Mark the breakpoint as disabled.

bpformat()

Return a string with all the information about the breakpoint, nicely formatted:

- Breakpoint number.
- Temporary status (del or keep).
- File/line position.
- Break condition.
- Number of times to ignore.
- Number of times hit.

New in version 3.2.

bpprint(*out*=*None*)

Print the output of **`bpformat()`** to the file *out*, or if it is `None`, to standard output.

`Breakpoint` instances have the following attributes:

file

File name of the **`Breakpoint`**.

line

Line number of the **`Breakpoint`** within **`file`**.

temporary

True if a **`Breakpoint`** at (file, line) is temporary.

cond

Condition for evaluating a **Breakpoint** at (file, line).

funcname

Function name that defines whether a **Breakpoint** is hit upon entering the function.

enabled

True if **Breakpoint** is enabled.

bpbynumber

Numeric index for a single instance of a **Breakpoint**.

bplist

Dictionary of **Breakpoint** instances indexed by (**file**, **line**) tuples.

ignore

Number of times to ignore a **Breakpoint**.

hits

Count of the number of times a **Breakpoint** has been hit.

class bdb.Bdb(*skip=None*)

The **Bdb** class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (**pdb.Pdb**) is an example.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

New in version 3.1: The *skip* argument.

The following methods of **Bdb** normally don't need to be overridden.

canonic(*filename*)

Return canonical form of *filename*.

For real file names, the canonical form is an operating-system-dependent, **case-normalized absolute path**. A *filename* with angle brackets, such as `"<stdin>"` generated in interactive mode, is returned unchanged.

reset()

Set the **botframe**, **stopframe**, **returnframe** and **quitting** attributes with values ready to start debugging.

trace_dispatch(*frame*, *event*, *arg*)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following:

- `"line"`: A new line of code is going to be executed.
- `"call"`: A function is about to be called, or another code block entered.
- `"return"`: A function or other code block is about to return.
- `"exception"`: An exception has occurred.
- `"c_call"`: A C function is about to be called.
- `"c_return"`: A C function has returned.
- `"c_exception"`: A C function has raised an

exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The *arg* parameter depends on the previous event.

See the documentation for **sys.settrace()** for more information on the trace function. For more information on code and frame objects, refer to The standard type hierarchy.

dispatch_line(*frame*)

If the debugger should stop on the current line, invoke the **user_line()** method (which should be overridden in subclasses). Raise a **BdbQuit** exception if the **Bdb.quitting** flag is set (which can be set from **user_line()**). Return a reference to the **trace_dispatch()** method for further tracing in that scope.

dispatch_call(*frame*, *arg*)

If the debugger should stop on this function call, invoke the **user_call()** method (which should be overridden in subclasses). Raise a **BdbQuit** exception if the **Bdb.quitting** flag is set (which can be set from **user_call()**). Return a reference to the **trace_dispatch()** method for further tracing in that scope.

dispatch_return(*frame*, *arg*)

If the debugger should stop on this function return, invoke the **user_return()** method (which should be overridden in subclasses). Raise a **BdbQuit** exception if the **Bdb.quitting** flag is set (which can be set from **user_return()**). Return a reference to the **trace_dispatch()** method for further tracing in that scope.

dispatch_exception(*frame*, *arg*)

If the debugger should stop at this exception, invokes the **`user_exception()`** method (which should be overridden in subclasses). Raise a **`BdbQuit`** exception if the **`Bdb.quitting`** flag is set (which can be set from **`user_exception()`**). Return a reference to the **`trace_dispatch()`** method for further tracing in that scope.

Normally derived classes don't override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

is_skipped_line(*module_name*)

Return True if *module_name* matches any skip pattern.

stop_here(*frame*)

Return True if *frame* is below the starting frame in the stack.

break_here(*frame*)

Return True if there is an effective breakpoint for this line.

Check whether a line or function breakpoint exists and is in effect. Delete temporary breakpoints based on information from **`effective()`**.

break_anywhere(*frame*)

Return True if any breakpoint exists for *frame*'s filename.

Derived classes should override these methods to gain control over debugger operation.

user_call(*frame*, *argument_list*)

Called from **`dispatch_call()`** if a break might stop

inside the called function.

user_line(*frame*)

Called from **`dispatch_line()`** when either **`stop_here()`** or **`break_here()`** returns `True`.

user_return(*frame*, *return_value*)

Called from **`dispatch_return()`** when **`stop_here()`** returns `True`.

user_exception(*frame*, *exc_info*)

Called from **`dispatch_exception()`** when **`stop_here()`** returns `True`.

do_clear(*arg*)

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

set_step()

Stop after one line of code.

set_next(*frame*)

Stop on the next line in or below the given frame.

set_return(*frame*)

Stop when returning from the given frame.

set_until(*frame*, *lineno*=*None*)

Stop when the line with the *lineno* greater than the current one is reached or when returning from current frame.

set_trace([*frame*])

Start debugging from *frame*. If *frame* is not specified, debugging starts from caller's frame.

set_continue()

Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to `None`.

set_quit()

Set the **`quitting`** attribute to `True`. This raises **`BdbQuit`** in the next call to one of the **`dispatch_*()`** methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or `None` if all is well.

set_break(*filename*, *lineno*, *temporary*=*False*, *cond*=*None*, *funcname*=*None*)

Set a new breakpoint. If the *lineno* line doesn't exist for the *filename* passed as argument, return an error message. The *filename* should be in canonical form, as described in the **`canonic()`** method.

clear_break(*filename*, *lineno*)

Delete the breakpoints in *filename* and *lineno*. If none were set, return an error message.

clear_bpbynumber(*arg*)

Delete the breakpoint which has the index *arg* in the **`Breakpoint.bpbynumber`**. If *arg* is not numeric or out of range, return an error message.

clear_all_file_breaks(*filename*)

Delete all breakpoints in *filename*. If none were set,

return an error message.

clear_all_breaks()

Delete all existing breakpoints. If none were set, return an error message.

get_bpbynumber(*arg*)

Return a breakpoint specified by the given number. If *arg* is a string, it will be converted to a number. If *arg* is a non-numeric string, if the given breakpoint never existed or has been deleted, a `ValueError` is raised.

New in version 3.2.

get_break(*filename*, *lineno*)

Return True if there is a breakpoint for *lineno* in *filename*.

get_breaks(*filename*, *lineno*)

Return all breakpoints for *lineno* in *filename*, or an empty list if none are set.

get_file_breaks(*filename*)

Return all breakpoints in *filename*, or an empty list if none are set.

get_all_breaks()

Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

get_stack(*f*, *t*)

Return a list of (frame, lineno) tuples in a stack trace, and a size.

The most recently called frame is last in the list. The

size is the number of frames below the frame where the debugger was invoked.

format_stack_entry(*frame_lineno*, *lprefix*=*': '*)

Return a string with information about a stack entry, which is a `(frame, lineno)` tuple. The return string contains:

- The canonical filename which contains the frame.
- The function name or `"<lambda>"`.
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a statement, given as a string.

run(*cmd*, *globals*=*None*, *locals*=*None*)

Debug a statement executed via the **`exec()`** function. *globals* defaults to **`__main__.__dict__`**, *locals* defaults to *globals*.

runeval(*expr*, *globals*=*None*, *locals*=*None*)

Debug an expression executed via the **`eval()`** function. *globals* and *locals* have the same meaning as in **`run()`**.

runctx(*cmd*, *globals*, *locals*)

For backwards compatibility. Calls the **`run()`** method.

runcall(*func*, */*, **args*, ***kwds*)

Debug a single function call, and return its result.

Finally, the module defines the following functions:

bdb.checkfuncname(*b*, *frame*)

Return True if we should break here, depending on the way

the **`Breakpoint`** *b* was set.

If it was set via line number, it checks if **`b.line`** is the same as the one in *frame*. If the breakpoint was set via **`function name`**, we have to check we are in the right *frame* (the right function) and if we are on its first executable line.

bdb.effective(*file*, *line*, *frame*)

Return `(active breakpoint, delete temporary flag)` or `(None, None)` as the breakpoint to act upon.

The *active breakpoint* is the first entry in **`bplist`** for the (**`file`**, **`line`**) (which must exist) that is **`enabled`**, for which **`checkfuncname()`** is True, and that has neither a False **`condition`** nor positive **`ignore`** count. The *flag*, meaning that a temporary breakpoint should be deleted, is False only when the **`cond`** cannot be evaluated (in which case, **`ignore`** count is ignored).

If no such entry exists, then (None, None) is returned.

bdb.set_trace()

Start debugging with a **`Bdb`** instance from caller's frame.

`faulthandler` — Dump the Python traceback

New in version 3.3.

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call `faulthandler.enable()` to install fault handlers for the **`SIGSEGV`**, **`SIGFPE`**, **`SIGABRT`**, **`SIGBUS`**, and **`SIGILL`** signals. You can also enable them at startup by setting the `PYTHONFAULTHANDLER` environment variable or by using the `-X faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the **`sigaltstack()`** function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The `backslashreplace` error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.
- The order is reversed: the most recent call is shown first.

By default, the Python traceback is written to `sys.stderr`. To see tracebacks, applications must be run in the terminal. A log file can alternatively be passed to `faulthandler.enable()`.

The module is implemented in C, so tracebacks can be dumped on a crash or when Python is deadlocked.

The Python Development Mode calls **`faulthandler.enable()`** at Python startup.

Dumping the traceback

faulthandler.dump_traceback(*file*=*sys.stderr*, *all_threads*=*True*)

Dump the tracebacks of all threads into *file*. If *all_threads* is `False`, dump only the current thread.

Changed in version 3.5: Added support for passing file descriptor to this function.

Fault handler state

faulthandler.enable(*file*=*sys.stderr*, *all_threads*=*True*)

Enable the fault handler: install handlers for the **`SIGSEGV`**, **`SIGFPE`**, **`SIGABRT`**, **`SIGBUS`** and **`SIGILL`** signals to dump the Python traceback. If *all_threads* is `True`, produce tracebacks for every running thread. Otherwise, dump only the current thread.

The *file* must be kept open until the fault handler is disabled: see issue with file descriptors.

Changed in version 3.5: Added support for passing file descriptor to this function.

Changed in version 3.6: On Windows, a handler for Windows exception is also installed.

Changed in version 3.10: The dump now mentions if a garbage collector collection is running if *all_threads* is true.

faulthandler.disable()

Disable the fault handler: uninstall the signal handlers

installed by **enable()**.

faulthandler.is_enabled()

Check if the fault handler is enabled.

Dumping the tracebacks after a timeout

faulthandler.dump_traceback_later(*timeout*, *repeat*=*False*, *file*=*sys.stderr*, *exit*=*False*)

Dump the tracebacks of all threads, after a timeout of *timeout* seconds, or every *timeout* seconds if *repeat* is `True`. If *exit* is `True`, call **_exit()** with status=1 after dumping the tracebacks. (Note **_exit()** exits the process immediately, which means it doesn't do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

The *file* must be kept open until the traceback is dumped or **cancel_dump_traceback_later()** is called: see issue with file descriptors.

This function is implemented using a watchdog thread.

Changed in version 3.7: This function is now always available.

Changed in version 3.5: Added support for passing file descriptor to this function.

faulthandler.cancel_dump_traceback_later()

Cancel the last call to **dump_traceback_later()**.

Dumping the traceback on a user signal

faulthandler.register(*signum*, *file*=*sys.stderr*, *all_threads*=*True*, *chain*=*False*)

Register a user signal: install a handler for the *signum* signal

to dump the traceback of all threads, or of the current thread if *all_threads* is `False`, into *file*. Call the previous handler if chain is `True`.

The *file* must be kept open until the signal is unregistered by **`unregister()`**: see issue with file descriptors.

Not available on Windows.

Changed in version 3.5: Added support for passing file descriptor to this function.

faulthandler.unregister(*signum*)

Unregister a user signal: uninstall the handler of the *signum* signal installed by **`register()`**. Return `True` if the signal was registered, `False` otherwise.

Not available on Windows.

Issue with file descriptors

`enable()`, **`dump_traceback_later()`** and **`register()`** keep the file descriptor of their *file* argument. If the file is closed and its file descriptor is reused by a new file, or if **`os.dup2()`** is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.

Example

Example of a segmentation fault on Linux with and without enabling the fault handler:

```
$ python3 -c "import ctypes; ctypes.string_at(0)"
Segmentation fault

$ python3 -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
```

```
Fatal Python error: Segmentation fault

Current thread 0x00007fb899f39700 (most recent call firs
  File "/home/python/cpython/Lib/ctypes/__init__.py", li
  File "<stdin>", line 1 in <module>
Segmentation fault
```

pdb — The Python Debugger

Source code: Lib/pdb.py [https://github.com/python/cpython/tree/3.11/Lib/pdb.py]

The module **pdb** defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible – it is actually defined as the class **Pdb**. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules **bdb** and **cmd**.

The debugger's prompt is `(Pdb)`. Typical usage to run a program under control of the debugger is:

```
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

Changed in version 3.3: Tab-completion via the **readline** module is available for commands and command arguments, e.g. the current global and local names are offered as arguments of the `p` command.

`pdb.py` can also be invoked as a script to debug other scripts. For

example:

```
python3 -m pdb myscript.py
```

When invoked as a script, pdb will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), pdb will restart the program. Automatic restarting preserves pdb's state (such as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

New in version 3.2: `pdb.py` now accepts a `-c` option that executes commands as if given in a `.pdbrc` file, see Debugger Commands.

New in version 3.7: `pdb.py` now accepts a `-m` option that execute modules similar to the way `python3 -m` does. As with a script, the debugger will pause execution just before the first line of the module.

The typical usage to break into the debugger is to insert:

```
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger, and then run the program. You can then step through the code following this statement, and continue running without the debugger using the **`continue`** command.

New in version 3.7: The built-in **`breakpoint()`**, when called with defaults, can be used instead of `import pdb; pdb.set_trace()`.

The typical usage to inspect a crashed program is:

```
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "./mymodule.py", line 4, in test
    test2()
```

```
  File "./mymodule.py", line 3, in test2
    print(spam)
NameError: spam
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print(spam)
(Pdb)
```

The module defines the following functions; each enters the debugger in a slightly different way:

pdb.run(*statement*, *globals*=*None*, *locals*=*None*)

Execute the *statement* (given as a string or a code object) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type **`continue`**, or you can step through the statement using **`step`** or **`next`** (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module **`__main__`** is used. (See the explanation of the built-in **`exec()`** or **`eval()`** functions.)

pdb.runeval(*expression*, *globals*=*None*, *locals*=*None*)

Evaluate the *expression* (given as a string or a code object) under debugger control. When **`runeval()`** returns, it returns the value of the expression. Otherwise this function is similar to **`run()`**.

pdb.runcall(*function*, **args*, ***kwds*)

Call the *function* (a function or method object, not a string) with the given arguments. When **`runcall()`** returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.

pdb.set_trace(***, *header*=*None*)

Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an

assertion fails). If given, *header* is printed to the console just before debugging begins.

Changed in version 3.7: The keyword-only argument *header*.

pdb.post_mortem(*traceback=None*)

Enter post-mortem debugging of the given *traceback* object. If no *traceback* is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

pdb.pm()

Enter post-mortem debugging of the traceback found in **sys.last_traceback**.

The `run*` functions and **set_trace()** are aliases for instantiating the **Pdb** class and calling the method of the same name. If you want to access further features, you have to do this yourself:

class pdb.Pdb(*completekey='tab', stdin=None, stdout=None, skip=None, nosigint=False, readrc=True*)

Pdb is the debugger class.

The *completekey*, *stdin* and *stdout* arguments are passed to the underlying **cmd.Cmd** class; see the description there.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. 1

By default, Pdb sets a handler for the SIGINT signal (which is sent when the user presses `Ctrl-C` on the console) when you give a `continue` command. This allows you to break into the debugger again by pressing `Ctrl-C`. If you want Pdb not to touch the SIGINT handler, set *nosigint* to true.

The *readrc* argument defaults to true and controls whether

Pdb will load .pdbrc files from the filesystem.

Example call to enable tracing with *skip*:

```
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

Raises an auditing event `pdb.Pdb` with no arguments.

New in version 3.1: The *skip* argument.

New in version 3.2: The *nosigint* argument. Previously, a SIGINT handler was never set by Pdb.

Changed in version 3.6: The *readrc* argument.

run(*statement*, *globals*=*None*, *locals*=*None*)
runeval(*expression*, *globals*=*None*, *locals*=*None*)
runcall(*function*, **args*, ***kwds*)
set_trace()

See the documentation for the functions explained above.

Debugger Commands

The commands recognized by the debugger are listed below. Most commands can be abbreviated to one or two letters as indicated; e.g. `h(elp)` means that either `h` or `help` can be used to enter the help command (but not `he` or `hel`, nor `H` or `Help` or `HELP`). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets (`[]`) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (`|`).

Entering a blank line repeats the last command entered. Exception: if the last command was a **`list`** command, the next 11 lines are listed.

Commands that the debugger doesn't recognize are assumed to be Python statements and are executed in the context of the program

being debugged. Python statements can also be prefixed with an exclamation point (`!`). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger's state is not changed.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

Multiple commands may be entered on a single line, separated by `;;`. (A single `;` is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first `;;` pair, even if it is in the middle of a quoted string. A workaround for strings with double semicolons is to use implicit string concatenation `';'';'` or `";"";"`.

If a file `.pdbrc` exists in the user's home directory or in the current directory, it is read with `'utf-8'` encoding and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

Changed in version 3.11: `.pdbrc` is now read with `'utf-8'` encoding. Previously, it was read with the system locale encoding.

Changed in version 3.2: `.pdbrc` can now contain commands that continue debugging, such as **`continue`** or **`next`**. Previously, these commands had no effect.

h(elp) [command]

Without argument, print the list of available commands. With a *command* as argument, print help about that command. `help pdb` displays the full documentation (the docstring of the **`pdb`** module). Since the *command* argument must be an identifier, `help exec` must be entered to get help on the `!` command.

w(here)

Print a stack trace, with the most recent frame at the bottom. An arrow indicates the current frame, which determines the context of most commands.

d(own) [count]

Move the current frame *count* (default one) levels down in the stack trace (to a newer frame).

u(p) [count]

Move the current frame *count* (default one) levels up in the stack trace (to an older frame).

b(reak) [([filename:]lineno | function) [, condition]]

With a *lineno* argument, set a break there in the current file. With a *function* argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn't been loaded yet). The file is searched on **`sys.path`**. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

tbreak [([filename:]lineno | function) [, condition]]

Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as for **`break`**.

cl(ear) [filename:lineno | bpnumber ...]

With a *filename:lineno* argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

disable [bpnumber ...]

Disable the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

enable [bpnumber ...]

Enable the breakpoints specified.

ignore bpnumber [count]

Set the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

condition bpnumber [condition]

Set a new *condition* for the breakpoint, an expression which must evaluate to true before the breakpoint is honored. If *condition* is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

commands [bpnumber]

Specify a list of commands for breakpoint number *bpnumber*. The commands themselves appear on the following lines. Type a line containing just `end` to terminate the commands. An example:

```
(Pdb) commands 1
(com) p some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type `commands` and follow it immediately with `end`; that is, give no commands.

With no *bpnumber* argument, `commands` refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the **`continue`** command, or **`step`**, or any other command that resumes execution.

Specifying any command resuming execution (currently **`continue`**, **`step`**, **`next`**, **`return`**, **`jump`**, **`quit`** and their abbreviations) terminates the command list (as if that command was immediately followed by end). This is because any time you resume execution (even with a simple next or step), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the 'silent' command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

s(tep)

Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

n(ext)

Continue execution until the next line in the current function is reached or it returns. (The difference between **`next`** and **`step`** is that **`step`** stops inside a called function, while **`next`** executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

unt(il) [lineno]

Without argument, continue execution until the line with a number greater than the current one is reached.

With a line number, continue execution until a line with a

number greater or equal to that is reached. In both cases, also stop when the current frame returns.

Changed in version 3.2: Allow giving an explicit line number.

r(eturn)

Continue execution until the current function returns.

c(ont(inue))

Continue execution, only stop when a breakpoint is encountered.

j(ump) lineno

Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don't want to run.

It should be noted that not all jumps are allowed – for instance it is not possible to jump into the middle of a `for` loop or out of a `finally` clause.

l(ist) [first[, last]]

List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With `.` as argument, list 11 lines around the current line. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

The current line in the current frame is indicated by `->`. If an exception is being debugged, the line where the exception was originally raised or propagated is indicated by `>>`, if it differs from the current line.

New in version 3.2: The `>>` marker.

ll | longlist

List all source code for the current function or frame.

Interesting lines are marked as for `list`.

New in version 3.2.

a(rgs)

Print the argument list of the current function.

p expression

Evaluate the *expression* in the current context and print its value.

Note

`print()` can also be used, but is not a debugger command — this executes the Python `print()` function.

pp expression

Like the `p` command, except the value of the expression is pretty-printed using the `pprint` module.

whatis expression

Print the type of the *expression*.

source expression

Try to get source code for the given object and display it.

New in version 3.2.

display [expression]

Display the value of the expression if it changed, each time execution stops in the current frame.

Without expression, list all display expressions for the current frame.

New in version 3.2.

undisplay [expression]

Do not display the expression any more in the current frame. Without expression, clear all display expressions for the current frame.

New in version 3.2.

interact

Start an interactive interpreter (using the `code` module) whose global namespace contains all the (global and local) names found in the current scope.

New in version 3.2.

alias [name [command]]

Create an alias called *name* that executes *command*. The command must *not* be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, and so on, while `%*` is replaced by all the parameters. If no command is given, the current alias for *name* is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands *can* be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the `.pdbrc` file):

```
# Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print("%1.",k
# Print instance variables in self
alias ps pi self
```

unalias name

Delete the specified alias.

! statement

Execute the (one-line) *statement* in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a **`global`** statement on the same line, e.g.:

```
(Pdb) global list_options; list_options = ['-l']
(Pdb)
```

run [args ...]
restart [args ...]

Restart the debugged Python program. If an argument is supplied, it is split with **`shlex`** and the result is used as the new **`sys.argv`**. History, breakpoints, actions and debugger options are preserved. **`restart`** is an alias for **`run`**.

q(uit)

Quit from the debugger. The program being executed is aborted.

debug code

Enter a recursive debugger that steps through the code argument (which is an arbitrary expression or statement to be executed in the current environment).

retval

Print the return value for the last return of a function.

Footnotes

1

Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

The Python Profilers

Source code: Lib/profile.py [https://github.com/python/cpython/tree/3.11/Lib/profile.py] and Lib/pstats.py [https://github.com/python/cpython/tree/3.11/Lib/pstats.py]

Introduction to the profilers

`cProfile` and **`profile`** provide *deterministic profiling* of Python programs. A *profile* is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the **`pstats`** module.

The Python standard library provides two different implementations of the same profiling interface:

1. **`cProfile`** is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on **`lsprof`**, contributed by Brett Rosen and Ted Czotter.
2. **`profile`**, a pure Python module whose interface is imitated by **`cProfile`**, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

Note

The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is **`timeit`** for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.

Instant User's Manual

This section is provided for users that "don't want to read the manual." It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")')
```

(Use **`profile`** instead of **`cProfile`** if the latter is not available on your system.)

The above action would run **`re.compile()`** and print profile results like the following:

```
         214 function calls (207 primitive calls) in 0.002

Ordered by: cumulative time

ncalls  tottime  percall  cumtime  percall filename:line
     1    0.000    0.000    0.002    0.002 {built-in met
     1    0.000    0.000    0.001    0.001 <string>:1(<m
     1    0.000    0.000    0.001    0.001 __init__.py:2
     1    0.000    0.000    0.001    0.001 __init__.py:2
     1    0.000    0.000    0.000    0.000 _compiler.py:
     1    0.000    0.000    0.000    0.000 _parser.py:93
     1    0.000    0.000    0.000    0.000 _compiler.py:
     1    0.000    0.000    0.000    0.000 _parser.py:43
```

The first line indicates that 214 calls were monitored. Of those calls, 207 were *primitive*, meaning that the call was not induced via recursion. The next line: `Ordered by: cumulative name`, indicates that the text string in the far right column was used to sort the output. The column headings include:

ncalls
: for the number of calls.

tottime
: for the total time spent in the given function (and excluding time made in calls to sub-functions)

percall
: is the quotient of `tottime` divided by `ncalls`

cumtime
: is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate *even* for recursive functions.

percall
: is the quotient of `cumtime` divided by primitive calls

filename:lineno(function)
: provides the respective data of each function

When there are two numbers in the first column (for example `3/1`), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the **`run()`** function:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")', 'restats')
```

The **`pstats.Stats`** class reads profile results from a file and formats them in various ways.

The files **`cProfile`** and **`profile`** can also be invoked as a script to profile another script. For example:

```
python -m cProfile [-o output_file] [-s sort_order] (-m
```

`-o` writes the profile results to a file instead of to stdout

`-s` specifies one of the **`sort_stats()`** sort values to sort the output by. This only applies when `-o` is not supplied.

`-m` specifies that a module is being profiled instead of a script.

> *New in version 3.7:* Added the `-m` option to **`cProfile`**.
>
> *New in version 3.8:* Added the `-m` option to **`profile`**.

The **`pstats`** module's **`Stats`** class has a variety of methods for manipulating and printing the data saved into a profile results file:

```
import pstats
from pstats import SortKey
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The **`strip_dirs()`** method removed the extraneous path from all the module names. The **`sort_stats()`** method sorted all the entries according to the standard module/line/name string that is printed. The **`print_stats()`** method printed out all the statistics. You might try the following sort calls:

```
p.sort_stats(SortKey.NAME)
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```
p.sort_stats(SortKey.CUMULATIVE).print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```
p.sort_stats(SortKey.TIME).print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```
p.sort_stats(SortKey.FILENAME).print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```
p.sort_stats(SortKey.TIME, SortKey.CUMULATIVE).print_sta
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: `.5`) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could now (`p` is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you're going to have to read the manual, or guess what the following functions do:

```
p.print_callees()
p.add('restats')
```

Invoked as a script, the **`pstats`** module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using **`cmd`**) and interactive help.

`profile` and **`cProfile`** Module Reference

Both the **profile** and **cProfile** modules provide the following functions:

profile.run(*command*, *filename*=*None*, *sort*=*-1*)

This function takes a single argument that can be passed to the **exec()** function, and an optional file name. In all cases this routine executes:

```
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a **Stats** instance and prints a simple profiling report. If the sort value is specified, it is passed to this **Stats** instance to control how the results are sorted.

profile.runctx(*command*, *globals*, *locals*, *filename*=*None*, *sort*=*-1*)

This function is similar to **run()**, with added arguments to supply the globals and locals dictionaries for the *command* string. This routine executes:

```
exec(command, globals, locals)
```

and gathers profiling statistics as in the **run()** function above.

class profile.Profile(*timer*=*None*, *timeunit*=*0.0*, *subcalls*=*True*, *builtins*=*True*)

This class is normally only used if more precise control over profiling is needed than what the **cProfile.run()** function provides.

A custom timer can be supplied for measuring how long code takes to run via the *timer* argument. This must be a function that returns a single number representing the current time. If the number is an integer, the *timeunit* specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the **Profile** class allows formatting profile results without writing the profile data to a file:

```
import cProfile, pstats, io
from pstats import SortKey
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = SortKey.CUMULATIVE
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print(s.getvalue())
```

The **Profile** class can also be used as a context manager (supported only in **cProfile** module. see Context Manager Types):

```
import cProfile

with cProfile.Profile() as pr:
    # ... do something ...

    pr.print_stats()
```

Changed in version 3.8: Added context manager support.

enable()

Start collecting profiling data. Only in **cProfile**.

disable()

Stop collecting profiling data. Only in **cProfile**.

create_stats()

Stop collecting profiling data and record the results internally as the current profile.

print_stats(*sort* = *-1*)

Create a **`Stats`** object based on the current profile and print the results to stdout.

dump_stats(*filename*)

Write the results of the current profile to *filename*.

run(*cmd*)

Profile the cmd via **`exec()`**.

runctx(*cmd*, *globals*, *locals*)

Profile the cmd via **`exec()`** with the specified global and local environment.

runcall(*func*, */*, **args*, ***kwargs*)

Profile `func(*args, **kwargs)`

Note that profiling will only work if the called command/function actually returns. If the interpreter is terminated (e.g. via a **`sys.exit()`** call during the called command/function execution) no profiling results will be printed.

The `Stats` Class

Analysis of the profiler data is done using the **`Stats`** class.

class pstats.Stats(**filenames or profile*, *stream* = *sys.stdout*)

This class constructor creates an instance of a "statistics object" from a *filename* (or list of filenames) or from a **`Profile`** instance. Output will be printed to the stream specified by *stream*.

The file selected by the above constructor must have been created by the corresponding version of **`profile`** or **`cProfile`**. To be specific, there is *no* file compatibility guaranteed with future versions of this profiler, and there is

no compatibility with files produced by other profilers, or the same profiler run on a different operating system. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing **Stats** object, the **add()** method can be used.

Instead of reading the profile data from a file, a **cProfile.Profile** or **profile.Profile** object can be used as the profile data source.

Stats objects have the following methods:

strip_dirs()

This method for the **Stats** class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its entries in a "random" order, as it was just after object initialization and loading. If **strip_dirs()** causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

add(**filenames*)

This method of the **Stats** class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of **profile.run()** or **cProfile.run()**. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

dump_stats(*filename*)

Save the data loaded into the **Stats** object to a file

named *filename*. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the **profile.Profile** and **cProfile.Profile** classes.

sort_stats(**keys*)

This method modifies the **Stats** object by sorting it according to the supplied criteria. The argument can be either a string or a SortKey enum identifying the basis of a sort (example: `'time'`, `'name'`, `SortKey.TIME` or `SortKey.NAME`). The SortKey enums argument have advantage over the string argument in that it is more robust and less error prone.

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, `sort_stats(SortKey.NAME, SortKey.FILE)` will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

For the string argument, abbreviations can be used for any key names, as long as the abbreviation is unambiguous.

The following are the valid string and SortKey:

Valid String Arg	Valid SortKey Arg
'calls'	SortKey.CALLS
'cumulative'	SortKey.CUMULATIVE
'cumtime'	
'file'	
'filename'	SortKey.FILENAME
'module'	
'ncalls'	
'pcalls'	SortKey.PCALLS
'line'	SortKey.LINE
'name'	SortKey.NAME
'nfl'	SortKey.NFL
'stdname'	SortKey.STDNAME
'time'	SortKey.TIME

Standard name	SortKey.STDNAME
Call count	SortKey.CALLS
Internal time	SortKey.TIME

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between `SortKey.NFL` and `SortKey.STDNAME` is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, `SortKey.NFL` does a numeric compare of the line numbers. In fact, `sort_stats(SortKey.NFL)` is the same as `sort_stats(SortKey.NAME, SortKey.FILENAME, SortKey.LINE)`.

For backward-compatibility reasons, the numeric arguments `-1`, `0`, `1`, and `2` are permitted. They are interpreted as `'stdname'`, `'calls'`, `'time'`, and `'cumulative'` respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

New in version 3.7: Added the SortKey enum.

reverse_order()

This method for the **`Stats`** class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

print_stats(**restrictions*)

This method for the **`Stats`** class prints out a report as described in the **`profile.run()`** definition.

The order of the printing is based on the last

sort_stats() operation done on the object (subject to caveats in **add()** and **strip_dirs()**).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a string that will interpreted as a regular expression (to pattern match the standard name that is printed). If several restrictions are provided, then they are applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `.*foo:`. In contrast, the command:

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names `.*foo:`, and then proceed to only print the first 10% of them.

print_callers(**restrictions*)

This method for the **Stats** class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by **print_stats()**, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With **profile**, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function

at the right.

- With **cProfile**, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.

print_callees(**restrictions*)

This method for the **Stats** class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the **print_callers()** method.

get_stats_profile()

This method returns an instance of StatsProfile, which contains a mapping of function names to instances of FunctionProfile. Each FunctionProfile instance holds information related to the function's profile such as how long the function took to run, how many times it was called, etc…

New in version 3.9: Added the following dataclasses: StatsProfile, FunctionProfile. Added the following function: get_stats_profile.

What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all *function call*, *function return*, and *exception* events are monitored, and precise timings are made for the intervals between these events (during which time the user's code is executing). In contrast, *statistical profiling* (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required in order to do deterministic profiling. Python automatically provides a *hook* (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify "hot loops" that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.

Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying "clock" is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the "error" will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it "takes a while" from when an event is dispatched until the profiler's call to get the time actually *gets* the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock's value was obtained (and then squirreled away), until the user's code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it *can* accumulate and become very significant.

The problem is more important with **profile** than with the lower-overhead **cProfile**. For this reason, **profile** provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-)) Do *not* be alarmed by negative numbers in the profile. They should *only* appear if you have calibrated your profiler, and the results are actually better than without calibration.

Calibration

The profiler of the **profile** module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see Limitations).

```
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running macOS, and using Python's time.process_time() as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is *very* fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```
import profile
```

```
# 1. Apply computed bias to all Profile instances create
profile.Profile.bias = your_computed_bias

# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias

# 3. Specify computed bias in instance constructor.
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will "less often" show up as negative in profile statistics.

Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the **`Profile`** class constructor:

```
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using **`profile.Profile`** or **`cProfile.Profile`**, `your_time_func`'s return value will be interpreted differently:

`profile.Profile`

> `your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what **`os.times()`** returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.
>
> Be warned that you should calibrate the profiler class for the timer function that you choose (see Calibration). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (**`os.times()`** is *pretty* bad, as it returns a tuple of

floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

cProfile.Profile

`your_time_func` should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the **`Profile`** instance as follows:

```
pr = cProfile.Profile(your_integer_time_func, 0.001
```

As the **`cProfile.Profile`** class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal **`_lsprof`** module.

Python 3.3 adds several new functions in **`time`** that can be used to make precise measurements of process or wall-clock time. For example, see **`time.perf_counter()`**.

`timeit` — Measure execution time of small code snippets

Source code: Lib/timeit.py [https://github.com/python/cpython/tree/3.11/Lib/timeit.py]

This module provides a simple way to time small bits of Python code. It has both a Command-Line Interface as well as a callable one. It avoids a number of common traps for measuring execution times. See also Tim Peters' introduction to the "Algorithms" chapter in the second edition of *Python Cookbook*, published by O'Reilly.

Basic Examples

The following example shows how the Command-Line Interface can be used to compare three different expressions:

```
$ python3 -m timeit '"-".join(str(n) for n in range(100)
10000 loops, best of 5: 30.2 usec per loop
$ python3 -m timeit '"-".join([str(n) for n in range(100
10000 loops, best of 5: 27.5 usec per loop
$ python3 -m timeit '"-".join(map(str, range(100)))'
10000 loops, best of 5: 23.2 usec per loop
```

This can be achieved from the Python Interface with:

```
>>> import timeit
>>> timeit.timeit('"-".join(str(n) for n in range(100))'
0.3018611848820001
>>> timeit.timeit('"-".join([str(n) for n in range(100)]
0.2727368790656328
>>> timeit.timeit('"-".join(map(str, range(100)))', numb
0.23702679807320237
```

A callable can also be passed from the Python Interface:

```
>>> timeit.timeit(lambda: "-".join(map(str, range(100))))
0.19665591977536678
```

Note however that `timeit()` will automatically determine the number of repetitions only when the command-line interface is used. In the Examples section you can find more advanced examples.

Python Interface

The module defines three convenience functions and a public class:

timeit.timeit(*stmt='pass'*, *setup='pass'*, *timer=<default timer>*, *number=1000000*, *globals=None*)

Create a `Timer` instance with the given statement, *setup* code and *timer* function and run its `timeit()` method with *number* executions. The optional *globals* argument specifies a namespace in which to execute the code.

Changed in version 3.5: The optional *globals* parameter was added.

timeit.repeat(*stmt='pass'*, *setup='pass'*, *timer=<default timer>*, *repeat=5*, *number=1000000*, *globals=None*)

Create a `Timer` instance with the given statement, *setup* code and *timer* function and run its `repeat()` method with the given *repeat* count and *number* executions. The optional *globals* argument specifies a namespace in which to execute the code.

Changed in version 3.5: The optional *globals* parameter was added.

Changed in version 3.7: Default value of *repeat* changed from 3 to 5.

timeit.default_timer()

The default timer, which is always `time.perf_counter()`.

Changed in version 3.3: `time.perf_counter()` is now the default timer.

class timeit.Timer(*stmt='pass'*, *setup='pass'*, *timer=<timer function>*, *globals=None*)

Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to `'pass'`; the timer function is platform-dependent (see the module doc string). *stmt* and *setup* may also contain multiple statements separated by `;` or newlines, as long as they don't contain multi-line string literals. The statement will by default be executed within timeit's namespace; this behavior can be controlled by passing a namespace to *globals*.

To measure the execution time of the first statement, use the `timeit()` method. The `repeat()` and `autorange()` methods are convenience methods to call `timeit()` multiple times.

The execution time of *setup* is excluded from the overall timed execution run.

The *stmt* and *setup* parameters can also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by `timeit()`. Note that the timing overhead is a little larger in this case because of the extra function calls.

Changed in version 3.5: The optional *globals* parameter was added.

timeit(*number=1000000*)

Time *number* executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of

times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement, the setup statement and the timer function to be used are passed to the constructor.

Note

By default, **`timeit()`** temporarily turns off garbage collection during the timing. The advantage of this approach is that it makes independent timings more comparable. The disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the *setup* string. For example:

```
timeit.Timer('for i in range(10): oct(i)', 'gc
```

autorange(*callback=None*)

Automatically determine how many times to call **`timeit()`**.

This is a convenience function that calls **`timeit()`** repeatedly so that the total time >= 0.2 second, returning the eventual (number of loops, time taken for that number of loops). It calls **`timeit()`** with increasing numbers from the sequence 1, 2, 5, 10, 20, 50, … until the time taken is at least 0.2 second.

If *callback* is given and is not `None`, it will be called after each trial with two arguments: `callback(number, time_taken)`.

New in version 3.6.

repeat(*repeat=5, number=1000000*)

Call **`timeit()`** a few times.

This is a convenience function that calls the **timeit()** repeatedly, returning a list of results. The first argument specifies how many times to call **timeit()**. The second argument specifies the *number* argument for **timeit()**.

Note

It's tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python's speed, but by other processes interfering with your timing accuracy. So the **min()** of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.

Changed in version 3.7: Default value of *repeat* changed from 3 to 5.

print_exc(*file=None*)

Helper to print a traceback from the timed code.

Typical use:

```
t = Timer(...)       # outside the try/except
try:
    t.timeit(...)    # or t.repeat(...)
except Exception:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional *file* argument directs where the traceback is sent; it defaults to **sys.stderr**.

Command-Line Interface

When called as a program from the command line, the following form is used:

```
python -m timeit [-n N] [-r N] [-u U] [-s S] [-h] [state
```

Where the following options are understood:

-n N, --number=N
: how many times to execute 'statement'

-r N, --repeat=N
: how many times to repeat the timer (default 5)

-s S, --setup=S
: statement to be executed once initially (default `pass`)

-p, --process
: measure process time, not wallclock time, using **`time.process_time()`** instead of **`time.perf_counter()`**, which is the default

  New in version 3.3.

-u, --unit=U
: specify a time unit for timer output; can select `nsec`, `usec`, `msec`, or `sec`

  New in version 3.5.

-v, --verbose
: print raw timing results; repeat for more digits precision

-h, --help
: print a short usage message and exit

A multi-line statement may be given by specifying each line as a

separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple **`-s`** options are treated similarly.

If **`-n`** is not given, a suitable number of loops is calculated by trying increasing numbers from the sequence 1, 2, 5, 10, 20, 50, … until the total time is at least 0.2 seconds.

`default_timer()` measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The **`-r`** option is good for this; the default of 5 repetitions is probably enough in most cases. You can use **`time.process_time()`** to measure CPU time.

Note

There is a certain baseline overhead associated with executing a pass statement. The code here doesn't try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions.

Examples

It is possible to provide a setup statement that is executed only once at the beginning:

```
$ python -m timeit -s 'text = "sample string"; char = "g
5000000 loops, best of 5: 0.0877 usec per loop
$ python -m timeit -s 'text = "sample string"; char = "g
1000000 loops, best of 5: 0.342 usec per loop
```

In the output, there are three fields. The loop count, which tells you how many times the statement body was run per timing loop repetition. The repetition count ('best of 5') which tells you how many times the timing loop was repeated, and finally the time the statement body took on average within the best repetition of the timing loop. That is, the time the fastest repetition took divided by

the loop count.

```
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "samp
1.7246671520006203
```

The same can be done using the **`Timer`** class and its methods:

```
>>> import timeit
>>> t = timeit.Timer('char in text', setup='text = "samp
>>> t.timeit()
0.3955516149999312
>>> t.repeat()
[0.40183617287970225, 0.37027556854118704, 0.38344867356
```

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using **`hasattr()`** vs. **`try`**/**`except`** to test for missing and present object attributes:

```
$ python -m timeit 'try:' '  str.__bool__' 'except Attri
20000 loops, best of 5: 15.7 usec per loop
$ python -m timeit 'if hasattr(str, "__bool__"): pass'
50000 loops, best of 5: 4.26 usec per loop

$ python -m timeit 'try:' '  int.__bool__' 'except Attri
200000 loops, best of 5: 1.43 usec per loop
$ python -m timeit 'if hasattr(int, "__bool__"): pass'
100000 loops, best of 5: 2.23 usec per loop
```

```
>>> import timeit
>>> # attribute is missing
>>> s = """\
... try:
...     str.__bool__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
```

```
0.9138244460009446
>>> s = "if hasattr(str, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.5829014980008651
>>>
>>> # attribute is present
>>> s = """\
... try:
...     int.__bool__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
0.04215312199994514
>>> s = "if hasattr(int, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.08588060699912603
```

To give the **`timeit`** module access to functions you define, you can pass a *setup* parameter which contains an import statement:

```
def test():
    """Stupid test function"""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ i
```

Another option is to pass **`globals()`** to the *globals* parameter, which will cause the code to be executed within your current global namespace. This can be more convenient than individually specifying imports:

```
def f(x):
    return x**2
def g(x):
    return x**4
def h(x):
```

```
    return x**8

import timeit
print(timeit.timeit('[func(42) for func in (f,g,h)]', gl
```

`trace` — Trace or track Python statement execution

Source code: Lib/trace.py [https://github.com/python/cpython/tree/3.11/Lib/trace.py]

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.

See also

Coverage.py **[https://coverage.readthedocs.io/]**
: A popular third-party coverage tool that provides HTML output along with advanced features such as branch coverage.

Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

--help
: Display usage and exit.

--version

Display the version of the module and exit.

New in version 3.8: Added `--module` option that allows to run an executable module.

Main options

At least one of the following options must be specified when invoking **`trace`**. The **`--listfuncs`** option is mutually exclusive with the **`--trace`** and **`--count`** options. When **`--listfuncs`** is provided, neither **`--count`** nor **`--trace`** are accepted, and vice versa.

-c, --count

Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also **`--coverdir`**, **`--file`** and **`--no-report`** below.

-t, --trace

Display lines as they are executed.

-l, --listfuncs

Display the functions executed by running the program.

-r, --report

Produce an annotated list from an earlier program run that used the **`--count`** and **`--file`** option. This does not execute any code.

-T, --trackcalls

Display the calling relationships exposed by running the program.

Modifiers

-f, --file=<file>

Name of a file to accumulate counts over several tracing runs.

Should be used with the **`--count`** option.

-C, --coverdir = <dir>

Directory where the report files go. The coverage report for `package.module` is written to file *`dir/package/module`*`.cover`.

-m, --missing

When generating annotated listings, mark lines which were not executed with `>>>>>>`.

-s, --summary

When using **`--count`** or **`--report`**, write a brief summary to stdout for each file processed.

-R, --no-report

Do not generate annotated listings. This is useful if you intend to make several runs with **`--count`**, and then produce a single set of annotated listings at the end.

-g, --timing

Prefix each line with the time since the program started. Only used while tracing.

Filters

These options may be repeated multiple times.

--ignore-module = <mod>

Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

--ignore-dir = <dir>

Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by **`os.pathsep`**.

Programmatic Interface

class trace.Trace(*count=1*, *trace=1*, *countfuncs=0*, *countcallers=0*, *ignoremods=()*, *ignoredirs=()*, *infile=None*, *outfile=None*, *timing=False*)

Create an object to trace execution of a single statement or expression. All parameters are optional. *count* enables counting of line numbers. *trace* enables line execution tracing. *countfuncs* enables listing of the functions called during the run. *countcallers* enables call relationship tracking. *ignoremods* is a list of modules or packages to ignore. *ignoredirs* is a list of directories whose modules or packages should be ignored. *infile* is the name of the file from which to read stored count information. *outfile* is the name of the file in which to write updated count information. *timing* enables a timestamp relative to when tracing was started to be displayed.

run(*cmd*)

Execute the command and gather statistics from the execution with the current tracing parameters. *cmd* must be a string or code object, suitable for passing into **`exec()`**.

runctx(*cmd*, *globals=None*, *locals=None*)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, *globals* and *locals* default to empty dictionaries.

runfunc(*func*, */*, **args*, ***kwds*)

Call *func* with the given arguments under control of the **`Trace`** object with the current tracing parameters.

results()

Return a **`CoverageResults`** object that contains the cumulative results of all previous calls to `run`, `runctx` and `runfunc` for the given **`Trace`** instance.

Does not reset the accumulated trace results.

class trace.CoverageResults

A container for coverage results, created by **`Trace.results()`**. Should not be created directly by the user.

update(*other*)

Merge in data from another **`CoverageResults`** object.

write_results(*show_missing* = *True*, *summary* = *False*, *coverdir* = *None*)

Write coverage results. Set *show_missing* to show lines that had no hits. Set *summary* to include in the output the coverage summary per module. *coverdir* specifies the directory into which the coverage result files will be output. If `None`, the results for each source file are placed in its directory.

A simple example demonstrating the use of the programmatic interface:

```
import sys
import trace

# create a Trace object, telling it what to ignore, and
# do tracing or line-counting or both.
tracer = trace.Trace(
    ignoredirs=[sys.prefix, sys.exec_prefix],
    trace=0,
    count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in the current directory
r = tracer.results()
```

```
r.write_results(show_missing=True, coverdir=".")
```

`tracemalloc` — Trace memory allocations

New in version 3.4.

Source code: Lib/tracemalloc.py [https://github.com/python/cpython/tree/3.11/Lib/tracemalloc.py]

The tracemalloc module is a debug tool to trace memory blocks allocated by Python. It provides the following information:

- Traceback where an object was allocated
- Statistics on allocated memory blocks per filename and per line number: total size, number and average size of allocated memory blocks
- Compute the differences between two snapshots to detect memory leaks

To trace most memory blocks allocated by Python, the module should be started as early as possible by setting the **PYTHONTRACEMALLOC** environment variable to `1`, or by using **-X** `tracemalloc` command line option. The **tracemalloc.start()** function can be called at runtime to start tracing Python memory allocations.

By default, a trace of an allocated memory block only stores the most recent frame (1 frame). To store 25 frames at startup: set the **PYTHONTRACEMALLOC** environment variable to `25`, or use the **-X** `tracemalloc=25` command line option.

Examples

Display the top 10

Display the 10 files allocating the most memory:

```
import tracemalloc

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('lineno')

print("[ Top 10 ]")
for stat in top_stats[:10]:
    print(stat)
```

Example of output of the Python test suite:

```
[ Top 10 ]
<frozen importlib._bootstrap>:716: size=4855 KiB, count=
<frozen importlib._bootstrap>:284: size=521 KiB, count=3
/usr/lib/python3.4/collections/__init__.py:368: size=244
/usr/lib/python3.4/unittest/case.py:381: size=185 KiB, c
/usr/lib/python3.4/unittest/case.py:402: size=154 KiB, c
/usr/lib/python3.4/abc.py:133: size=88.7 KiB, count=347,
<frozen importlib._bootstrap>:1446: size=70.4 KiB, count
<frozen importlib._bootstrap>:1454: size=52.0 KiB, count
<string>:5: size=49.7 KiB, count=148, average=344 B
/usr/lib/python3.4/sysconfig.py:411: size=48.0 KiB, coun
```

We can see that Python loaded `4855 KiB` data (bytecode and constants) from modules and that the **`collections`** module allocated `244 KiB` to build **`namedtuple`** types.

See **`Snapshot.statistics()`** for more options.

Compute differences

Take two snapshots and display the differences:

```
import tracemalloc
```

```
tracemalloc.start()
# ... start your application ...

snapshot1 = tracemalloc.take_snapshot()
# ... call the function leaking memory ...
snapshot2 = tracemalloc.take_snapshot()

top_stats = snapshot2.compare_to(snapshot1, 'lineno')

print("[ Top 10 differences ]")
for stat in top_stats[:10]:
    print(stat)
```

Example of output before/after running some tests of the Python test suite:

```
[ Top 10 differences ]
<frozen importlib._bootstrap>:716: size=8173 KiB (+4428
/usr/lib/python3.4/linecache.py:127: size=940 KiB (+940
/usr/lib/python3.4/unittest/case.py:571: size=298 KiB (+
<frozen importlib._bootstrap>:284: size=1005 KiB (+166 K
/usr/lib/python3.4/mimetypes.py:217: size=112 KiB (+112
/usr/lib/python3.4/http/server.py:848: size=96.0 KiB (+9
/usr/lib/python3.4/inspect.py:1465: size=83.5 KiB (+83.5
/usr/lib/python3.4/unittest/mock.py:491: size=77.7 KiB (
/usr/lib/python3.4/urllib/parse.py:476: size=71.8 KiB (+
/usr/lib/python3.4/contextlib.py:38: size=67.2 KiB (+67.
```

We can see that Python has loaded `8173 KiB` of module data (bytecode and constants), and that this is `4428 KiB` more than had been loaded before the tests, when the previous snapshot was taken. Similarly, the **`linecache`** module has cached `940 KiB` of Python source code to format tracebacks, all of it since the previous snapshot.

If the system has little free memory, snapshots can be written on disk using the **`Snapshot.dump()`** method to analyze the snapshot offline. Then use the **`Snapshot.load()`** method reload the snapshot.

Get the traceback of a memory block

Code to display the traceback of the biggest memory block:

```
import tracemalloc

# Store 25 frames
tracemalloc.start(25)

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('traceback')

# pick the biggest memory block
stat = top_stats[0]
print("%s memory blocks: %.1f KiB" % (stat.count, stat.s
for line in stat.traceback.format():
    print(line)
```

Example of output of the Python test suite (traceback limited to 25 frames):

```
903 memory blocks: 870.1 KiB
  File "<frozen importlib._bootstrap>", line 716
  File "<frozen importlib._bootstrap>", line 1036
  File "<frozen importlib._bootstrap>", line 934

```

We can see that the most memory was allocated in the **`importlib`** module to load data (bytecode and constants) from modules: `870.1 KiB`. The traceback is where the **`importlib`** loaded data most recently: on the `import pdb` line of the **`doctest`** module. The traceback may change if a new module is loaded.

Pretty top

Code to display the 10 lines allocating the most memory with a pretty output, ignoring `<frozen importlib._bootstrap>` and `<unknown>` files:

```
import linecache
import os
import tracemalloc

def display_top(snapshot, key_type='lineno', limit=10):
    snapshot = snapshot.filter_traces((
        tracemalloc.Filter(False, "<frozen importlib._bo
        tracemalloc.Filter(False, "<unknown>"),
```

```
    ))
    top_stats = snapshot.statistics(key_type)

    print("Top %s lines" % limit)
    for index, stat in enumerate(top_stats[:limit], 1):
        frame = stat.traceback[0]
        print("#%s: %s:%s: %.1f KiB"
              % (index, frame.filename, frame.lineno, st
        line = linecache.getline(frame.filename, frame.l
        if line:
            print('    %s' % line)

    other = top_stats[limit:]
    if other:
        size = sum(stat.size for stat in other)
        print("%s other: %.1f KiB" % (len(other), size /
    total = sum(stat.size for stat in top_stats)
    print("Total allocated size: %.1f KiB" % (total / 10

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
display_top(snapshot)
```

Example of output of the Python test suite:

```
Top 10 lines
#1: Lib/base64.py:414: 419.8 KiB
    _b85chars2 = [(a + b) for a in _b85chars for b in _b
#2: Lib/base64.py:306: 419.8 KiB
    _a85chars2 = [(a + b) for a in _a85chars for b in _a
#3: collections/__init__.py:368: 293.6 KiB
    exec(class_definition, namespace)
#4: Lib/abc.py:133: 115.2 KiB
    cls = super().__new__(mcls, name, bases, namespace)
#5: unittest/case.py:574: 103.1 KiB
    testMethod()
```

```
#6: Lib/linecache.py:127: 95.4 KiB
    lines = fp.readlines()
#7: urllib/parse.py:476: 71.8 KiB
    for a in _hexdig for b in _hexdig}
#8: <string>:5: 62.0 KiB
#9: Lib/_weakrefset.py:37: 60.0 KiB
    self.data = set()
#10: Lib/base64.py:142: 59.8 KiB
    _b32tab2 = [a + b for a in _b32tab for b in _b32tab]
6220 other: 3602.8 KiB
Total allocated size: 5303.1 KiB
```

See **`Snapshot.statistics()`** for more options.

Record the current and peak size of all traced memory blocks

The following code computes two sums like `0 + 1 + 2 + ...` inefficiently, by creating a list of those numbers. This list consumes a lot of memory temporarily. We can use **`get_traced_memory()`** and **`reset_peak()`** to observe the small memory usage after the sum is computed as well as the peak memory usage during the computations:

```
import tracemalloc

tracemalloc.start()

# Example code: compute a sum with a large temporary lis
large_sum = sum(list(range(100000)))

first_size, first_peak = tracemalloc.get_traced_memory()

tracemalloc.reset_peak()

# Example code: compute a sum with a small temporary lis
small_sum = sum(list(range(1000)))

second_size, second_peak = tracemalloc.get_traced_memory
```

```
print(f"{first_size=}, {first_peak=}")
print(f"{second_size=}, {second_peak=}")
```

Output:

```
first_size=664, first_peak=3592984
second_size=804, second_peak=29704
```

Using **`reset_peak()`** ensured we could accurately record the peak during the computation of `small_sum`, even though it is much smaller than the overall peak size of memory blocks since the **`start()`** call. Without the call to **`reset_peak()`**, `second_peak` would still be the peak from the computation `large_sum` (that is, equal to `first_peak`). In this case, both peaks are much higher than the final memory usage, and which suggests we could optimise (by removing the unnecessary call to **`list`**, and writing `sum(range(...))`).

API

Functions

tracemalloc.clear_traces()

Clear traces of memory blocks allocated by Python.

See also **`stop()`**.

tracemalloc.get_object_traceback(*obj*)

Get the traceback where the Python object *obj* was allocated. Return a **`Traceback`** instance, or `None` if the **`tracemalloc`** module is not tracing memory allocations or did not trace the allocation of the object.

See also **`gc.get_referrers()`** and **`sys.getsizeof()`** functions.

tracemalloc.get_traceback_limit()

Get the maximum number of frames stored in the traceback

of a trace.

The **tracemalloc** module must be tracing memory allocations to get the limit, otherwise an exception is raised.

The limit is set by the **start()** function.

tracemalloc.get_traced_memory()

Get the current size and peak size of memory blocks traced by the **tracemalloc** module as a tuple: `(current: int, peak: int)`.

tracemalloc.reset_peak()

Set the peak size of memory blocks traced by the **tracemalloc** module to the current size.

Do nothing if the **tracemalloc** module is not tracing memory allocations.

This function only modifies the recorded peak size, and does not modify or clear any traces, unlike **clear_traces()**. Snapshots taken with **take_snapshot()** before a call to **reset_peak()** can be meaningfully compared to snapshots taken after the call.

See also **get_traced_memory()**.

New in version 3.9.

tracemalloc.get_tracemalloc_memory()

Get the memory usage in bytes of the **tracemalloc** module used to store traces of memory blocks. Return an **int**.

tracemalloc.is_tracing()

`True` if the **tracemalloc** module is tracing Python memory allocations, `False` otherwise.

See also **start()** and **stop()** functions.

tracemalloc.start(*nframe: int = 1*)

Start tracing Python memory allocations: install hooks on Python memory allocators. Collected tracebacks of traces will be limited to *nframe* frames. By default, a trace of a memory block only stores the most recent frame: the limit is `1`. *nframe* must be greater or equal to `1`.

You can still read the original number of total frames that composed the traceback by looking at the **`Traceback.total_nframe`** attribute.

Storing more than `1` frame is only useful to compute statistics grouped by `'traceback'` or to compute cumulative statistics: see the **`Snapshot.compare_to()`** and **`Snapshot.statistics()`** methods.

Storing more frames increases the memory and CPU overhead of the **`tracemalloc`** module. Use the **`get_tracemalloc_memory()`** function to measure how much memory is used by the **`tracemalloc`** module.

The **`PYTHONTRACEMALLOC`** environment variable (`PYTHONTRACEMALLOC=NFRAME`) and the **`-X`** `tracemalloc=NFRAME` command line option can be used to start tracing at startup.

See also **`stop()`**, **`is_tracing()`** and **`get_traceback_limit()`** functions.

tracemalloc.stop()

Stop tracing Python memory allocations: uninstall hooks on Python memory allocators. Also clears all previously collected traces of memory blocks allocated by Python.

Call **`take_snapshot()`** function to take a snapshot of traces before clearing them.

See also **`start()`**, **`is_tracing()`** and **`clear_traces()`** functions.

tracemalloc.take_snapshot()

Take a snapshot of traces of memory blocks allocated by Python. Return a new **Snapshot** instance.

The snapshot does not include memory blocks allocated before the **tracemalloc** module started to trace memory allocations.

Tracebacks of traces are limited to **get_traceback_limit()** frames. Use the *nframe* parameter of the **start()** function to store more frames.

The **tracemalloc** module must be tracing memory allocations to take a snapshot, see the **start()** function.

See also the **get_object_traceback()** function.

DomainFilter

class tracemalloc.DomainFilter(*inclusive: bool*, *domain: int*)

Filter traces of memory blocks by their address space (domain).

New in version 3.6.

inclusive

If *inclusive* is `True` (include), match memory blocks allocated in the address space **domain**.

If *inclusive* is `False` (exclude), match memory blocks not allocated in the address space **domain**.

domain

Address space of a memory block (`int`). Read-only property.

Filter

class tracemalloc.Filter(*inclusive: bool*, *filename_pattern: str*, *lineno: int*

= *None*, *all_frames:* *bool* = *False*, *domain:* *int* = *None*)

Filter on traces of memory blocks.

See the **`fnmatch.fnmatch()`** function for the syntax of *filename_pattern*. The `'.pyc'` file extension is replaced with `'.py'`.

Examples:

- `Filter(True, subprocess.__file__)` only includes traces of the **`subprocess`** module
- `Filter(False, tracemalloc.__file__)` excludes traces of the **`tracemalloc`** module
- `Filter(False, "<unknown>")` excludes empty tracebacks

Changed in version 3.5: The `'.pyo'` file extension is no longer replaced with `'.py'`.

Changed in version 3.6: Added the **`domain`** attribute.

domain

Address space of a memory block (`int` or `None`).

tracemalloc uses the domain `0` to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

inclusive

If *inclusive* is `True` (include), only match memory blocks allocated in a file with a name matching **`filename_pattern`** at line number **`lineno`**.

If *inclusive* is `False` (exclude), ignore memory blocks allocated in a file with a name matching **`filename_pattern`** at line number **`lineno`**.

lineno

Line number (`int`) of the filter. If *lineno* is `None`, the filter matches any line number.

filename_pattern

Filename pattern of the filter (`str`). Read-only property.

all_frames

If *all_frames* is `True`, all frames of the traceback are checked. If *all_frames* is `False`, only the most recent frame is checked.

This attribute has no effect if the traceback limit is `1`. See the **`get_traceback_limit()`** function and **`Snapshot.traceback_limit`** attribute.

Frame

class tracemalloc.Frame

Frame of a traceback.

The **`Traceback`** class is a sequence of **`Frame`** instances.

filename

Filename (`str`).

lineno

Line number (`int`).

Snapshot

class tracemalloc.Snapshot

Snapshot of traces of memory blocks allocated by Python.

The **`take_snapshot()`** function creates a snapshot instance.

compare_to(*old_snapshot: Snapshot*, *key_type: str*, *cumulative: bool = False*)

Compute the differences with an old snapshot. Get statistics as a sorted list of **`StatisticDiff`** instances

grouped by *key_type*.

See the `Snapshot.statistics()` method for *key_type* and *cumulative* parameters.

The result is sorted from the biggest to the smallest by: absolute value of `StatisticDiff.size_diff`, `StatisticDiff.size`, absolute value of `StatisticDiff.count_diff`, `Statistic.count` and then by `StatisticDiff.traceback`.

dump(*filename*)

Write the snapshot into a file.

Use `load()` to reload the snapshot.

filter_traces(*filters*)

Create a new `Snapshot` instance with a filtered `traces` sequence, *filters* is a list of `DomainFilter` and `Filter` instances. If *filters* is an empty list, return a new `Snapshot` instance with a copy of the traces.

All inclusive filters are applied at once, a trace is ignored if no inclusive filters match it. A trace is ignored if at least one exclusive filter matches it.

Changed in version 3.6: `DomainFilter` instances are now also accepted in *filters*.

classmethod load(*filename*)

Load a snapshot from a file.

See also `dump()`.

statistics(*key_type: str*, *cumulative: bool* = *False*)

Get statistics as a sorted list of `Statistic` instances grouped by *key_type*:

key_type	description

filename	`'filename'`
filename and line number	`'lineno'`
traceback	`'traceback'`

If *cumulative* is `True`, cumulate size and count of memory blocks of all frames of the traceback of a trace, not only the most recent frame. The cumulative mode can only be used with *key_type* equals to `'filename'` and `'lineno'`.

The result is sorted from the biggest to the smallest by: **`Statistic.size`**, **`Statistic.count`** and then by **`Statistic.traceback`**.

traceback_limit

Maximum number of frames stored in the traceback of **`traces`**: result of the **`get_traceback_limit()`** when the snapshot was taken.

traces

Traces of all memory blocks allocated by Python: sequence of **`Trace`** instances.

The sequence has an undefined order. Use the **`Snapshot.statistics()`** method to get a sorted list of statistics.

Statistic

class tracemalloc.Statistic

Statistic on memory allocations.

`Snapshot.statistics()` returns a list of **`Statistic`** instances.

See also the **`StatisticDiff`** class.

count

Number of memory blocks (`int`).

size

Total size of memory blocks in bytes (`int`).

traceback

Traceback where the memory block was allocated, **`Traceback`** instance.

StatisticDiff

class tracemalloc.StatisticDiff

Statistic difference on memory allocations between an old and a new **`Snapshot`** instance.

`Snapshot.compare_to()` returns a list of **`StatisticDiff`** instances. See also the **`Statistic`** class.

count

Number of memory blocks in the new snapshot (`int`): `0` if the memory blocks have been released in the new snapshot.

count_diff

Difference of number of memory blocks between the old and the new snapshots (`int`): `0` if the memory blocks have been allocated in the new snapshot.

size

Total size of memory blocks in bytes in the new snapshot (`int`): `0` if the memory blocks have been released in the new snapshot.

size_diff

Difference of total size of memory blocks in bytes between the old and the new snapshots (`int`): `0` if the memory blocks have been allocated in the new snapshot.

traceback

Traceback where the memory blocks were allocated, **Traceback** instance.

Trace

class tracemalloc.Trace

Trace of a memory block.

The **Snapshot.traces** attribute is a sequence of **Trace** instances.

Changed in version 3.6: Added the **domain** attribute.

domain

Address space of a memory block (`int`). Read-only property.

tracemalloc uses the domain `0` to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

size

Size of the memory block in bytes (`int`).

traceback

Traceback where the memory block was allocated, **Traceback** instance.

Traceback

class tracemalloc.Traceback

Sequence of **Frame** instances sorted from the oldest frame to the most recent frame.

A traceback contains at least `1` frame. If the `tracemalloc` module failed to get a frame, the filename `"<unknown>"` at line number `0` is used.

When a snapshot is taken, tracebacks of traces are limited to

get_traceback_limit() frames. See the **take_snapshot()** function. The original number of frames of the traceback is stored in the **Traceback.total_nframe** attribute. That allows to know if a traceback has been truncated by the traceback limit.

The **Trace.traceback** attribute is an instance of **Traceback** instance.

Changed in version 3.7: Frames are now sorted from the oldest to the most recent, instead of most recent to oldest.

total_nframe

Total number of frames that composed the traceback before truncation. This attribute can be set to `None` if the information is not available.

Changed in version 3.9: The **Traceback.total_nframe** attribute was added.

format(*limit=None*, *most_recent_first=False*)

Format the traceback as a list of lines. Use the **linecache** module to retrieve lines from the source code. If *limit* is set, format the *limit* most recent frames if *limit* is positive. Otherwise, format the `abs(limit)` oldest frames. If *most_recent_first* is `True`, the order of the formatted frames is reversed, returning the most recent frame first instead of last.

Similar to the **traceback.format_tb()** function, except that **format()** does not include newlines.

Example:

```
print("Traceback (most recent call first):")
for line in traceback:
    print(line)
```

Output:

```
Traceback (most recent call first):
  File "test.py", line 9
    obj = Object()
  File "test.py", line 12
    tb = tracemalloc.get_object_traceback(f())
```

Software Packaging and Distribution

These libraries help you with publishing and installing Python software. While these modules are designed to work in conjunction with the Python Package Index [https://pypi.org], they can also be used with a local index server, or without any index server at all.

`distutils` — Building and installing Python modules

`distutils` is deprecated with removal planned for Python 3.12. See the What's New entry for more information.

The **`distutils`** package provides support for building and installing additional modules into a Python installation. The new modules may be either 100%-pure Python, or may be extension modules written in C, or may be collections of Python packages which include modules coded in both Python and C.

Most Python users will *not* want to use this module directly, but instead use the cross-version tools maintained by the Python Packaging Authority. In particular, setuptools [https://setuptools.readthedocs.io/en/latest/] is an enhanced alternative to **`distutils`** that provides:

- support for declaring project dependencies
- additional mechanisms for configuring which files to include in source releases (including plugins for integration with version control systems)
- the ability to declare project "entry points", which can be used as the basis for application plugin systems
- the ability to automatically generate Windows command line executables at installation time rather than needing to prebuild them
- consistent behaviour across all supported Python versions

The recommended pip [https://pip.pypa.io/] installer runs all `setup.py` scripts with `setuptools`, even if the script itself only imports `distutils`. Refer to the Python Packaging User Guide [https://packaging.python.org] for more information.

For the benefits of packaging tool authors and users seeking a deeper understanding of the details of the current packaging and distribution system, the legacy `distutils` based user documentation and API reference remain available:

- Installing Python Modules (Legacy version)
- Distributing Python Modules (Legacy version)

`ensurepip` — Bootstrapping the `pip` installer

New in version 3.4.

Source code: Lib/ensurepip [https://github.com/python/cpython/tree/3.11/Lib/ensurepip]

The `ensurepip` package provides support for bootstrapping the `pip` installer into an existing Python installation or virtual environment. This bootstrapping approach reflects the fact that `pip` is an independent project with its own release cycle, and the latest available stable version is bundled with maintenance and feature releases of the CPython reference interpreter.

In most cases, end users of Python shouldn't need to invoke this module directly (as `pip` should be bootstrapped by default), but it may be needed if installing `pip` was skipped when installing Python (or when creating a virtual environment) or after explicitly uninstalling `pip`.

Note

This module *does not* access the internet. All of the components needed to bootstrap `pip` are included as internal parts of the package.

See also

Installing Python Modules
The end user guide for installing Python packages

PEP 453 [https://peps.python.org/pep-0453/]: Explicit bootstrapping of pip in Python installations

The original rationale and specification for this module.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Command line interface

The command line interface is invoked using the interpreter's `-m` switch.

The simplest possible invocation is:

```
python -m ensurepip
```

This invocation will install `pip` if it is not already installed, but otherwise does nothing. To ensure the installed version of `pip` is at least as recent as the one available in `ensurepip`, pass the `--upgrade` option:

```
python -m ensurepip --upgrade
```

By default, `pip` is installed into the current virtual environment (if one is active) or into the system site packages (if there is no active virtual environment). The installation location can be controlled through two additional command line options:

- `--root <dir>`: Installs `pip` relative to the given root directory rather than the root of the currently active virtual environment (if any) or the default root for the current Python installation.
- `--user`: Installs `pip` into the user site packages directory rather than globally for the current Python installation (this option is not permitted inside an active virtual environment).

By default, the scripts `pipX` and `pipX.Y` will be installed (where X.Y stands for the version of Python used to invoke `ensurepip`).

The scripts installed can be controlled through two additional command line options:

- `--altinstall`: if an alternate installation is requested, the `pipX` script will *not* be installed.
- `--default-pip`: if a "default pip" installation is requested, the `pip` script will be installed in addition to the two regular scripts.

Providing both of the script selection options will trigger an exception.

Module API

`ensurepip` exposes two functions for programmatic use:

ensurepip.version()

Returns a string specifying the available version of pip that will be installed when bootstrapping an environment.

ensurepip.bootstrap(*root=None*, *upgrade=False*, *user=False*, *altinstall=False*, *default_pip=False*, *verbosity=0*)

Bootstraps `pip` into the current or designated environment.

root specifies an alternative root directory to install relative to. If *root* is `None`, then installation uses the default install location for the current environment.

upgrade indicates whether or not to upgrade an existing installation of an earlier version of `pip` to the available version.

user indicates whether to use the user scheme rather than installing globally.

By default, the scripts `pipX` and `pipX.Y` will be installed (where X.Y stands for the current version of Python).

If *altinstall* is set, then `pipX` will *not* be installed.

If *default_pip* is set, then `pip` will be installed in addition to the two regular scripts.

Setting both *altinstall* and *default_pip* will trigger **`ValueError`**.

verbosity controls the level of output to **`sys.stdout`** from the bootstrapping operation.

Raises an auditing event `ensurepip.bootstrap` with argument `root`.

Note

The bootstrapping process has side effects on both `sys.path` and `os.environ`. Invoking the command line interface in a subprocess instead allows these side effects to be avoided.

Note

The bootstrapping process may install additional modules required by `pip`, but other software should not assume those dependencies will always be present by default (as the dependencies may be removed in a future version of `pip`).

`venv` — Creation of virtual environments

New in version 3.3.

Source code: Lib/venv/ [https://github.com/python/cpython/tree/3.11/Lib/venv/]

The `venv` module supports creating lightweight "virtual environments", each with their own independent set of Python packages installed in their `site` directories. A virtual environment is created on top of an existing Python installation, known as the virtual environment's "base" Python, and may optionally be isolated from the packages in the base environment, so only those explicitly installed in the virtual environment are available.

When used from within a virtual environment, common installation tools such as pip [https://pypi.org/project/pip/] will install Python packages into a virtual environment without needing to be told to do so explicitly.

See **PEP 405** [https://peps.python.org/pep-0405/] for more background on Python virtual environments.

See also

Python Packaging User Guide: Creating and using virtual environments [https://packaging.python.org/guides/installing-using-pip-and-virtual-environments/#creating-a-virtual-environment]

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Creating virtual environments

Creation of virtual environments is done by executing the command `venv`:

```
python3 -m venv /path/to/new/virtual/environment
```

Running this command creates the target directory (creating any parent directories that don't exist already) and places a `pyvenv.cfg` file in it with a `home` key pointing to the Python installation from which the command was run (a common name for the target directory is `.venv`). It also creates a `bin` (or `Scripts` on Windows) subdirectory containing a copy/symlink of the Python binary/binaries (as appropriate for the platform or arguments used at environment creation time). It also creates an (initially empty) `lib/pythonX.Y/site-packages` subdirectory (on Windows, this is `Lib\site-packages`). If an existing directory is specified, it will be re-used.

Deprecated since version 3.6: `pyvenv` was the recommended tool for creating virtual environments for Python 3.3 and 3.4, and is deprecated in Python 3.6.

Changed in version 3.5: The use of `venv` is now recommended for creating virtual environments.

On Windows, invoke the `venv` command as follows:

```
c:\>c:\Python35\python -m venv c:\path\to\myenv
```

Alternatively, if you configured the `PATH` and `PATHEXT` variables for your Python installation:

```
c:\>python -m venv c:\path\to\myenv
```

The command, if run with `-h`, will show the available options:

```
usage: venv [-h] [--system-site-packages] [--symlinks |
            [--upgrade] [--without-pip] [--prompt PROMPT
            ENV_DIR [ENV_DIR ...]
```

```
Creates virtual Python environments in one or more targe

positional arguments:
  ENV_DIR               A directory to create the enviro

optional arguments:

                        of Python, assuming Python has b
  --without-pip         Skips installing or upgrading pi
                        environment (pip is bootstrapped
  --prompt PROMPT       Provides an alternative prompt p
                        environment.
  --upgrade-deps        Upgrade core dependencies: pip s
                        latest version in PyPI

Once an environment has been created, you may wish to ac
sourcing an activate script in its bin directory.
```

Changed in version 3.9: Add `--upgrade-deps` option to upgrade pip + setuptools to the latest on PyPI

Changed in version 3.4: Installs pip by default, added the `--without-pip` and `--copies` options

Changed in version 3.4: In earlier versions, if the target directory already existed, an error was raised, unless the `--clear` or `--upgrade` option was provided.

Note

While symlinks are supported on Windows, they are not recommended. Of particular note is that double-clicking `python.exe` in File Explorer will resolve the symlink eagerly and ignore the virtual environment.

Note

On Microsoft Windows, it may be required to enable the `Activate.ps1` script by setting the execution policy for the user. You can do this by issuing the following PowerShell command:

PS C:> Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser

See About Execution Policies [https://go.microsoft.com/fwlink/?LinkID=135170] for more information.

The created `pyvenv.cfg` file also includes the `include-system-site-packages` key, set to `true` if `venv` is run with the `--system-site-packages` option, `false` otherwise.

Unless the `--without-pip` option is given, **`ensurepip`** will be invoked to bootstrap `pip` into the virtual environment.

Multiple paths can be given to `venv`, in which case an identical virtual environment will be created, according to the given options, at each provided path.

How venvs work

When a Python interpreter is running from a virtual environment, **`sys.prefix`** and **`sys.exec_prefix`** point to the directories of the virtual environment, whereas **`sys.base_prefix`** and **`sys.base_exec_prefix`** point to those of the base Python used to create the environment. It is sufficient to check `sys.prefix == sys.base_prefix` to determine if the current interpreter is

running from a virtual environment.

A virtual environment may be “activated” using a script in its binary directory (`bin` on POSIX; `Scripts` on Windows). This will prepend that directory to your **PATH**, so that running **!python** will invoke the environment’s Python interpreter and you can run installed scripts without having to use their full path. The invocation of the activation script is platform-specific (*<venv>* must be replaced by the path to the directory containing the virtual environment):

Platform	Shell	Command to activate virtual environment
POSIX	bash/zsh	`$ source <venv>/bin/activate`
	fish	`$ source <venv>/bin/activate.fish`
	csh/tcsh	`$ source <venv>/bin/activate.csh`
	PowerShell	`$ <venv>/bin/Activate.ps1`
Windows	cmd.exe	`C:\> <venv>\Scripts\activate.bat`
	PowerShell	`PS C:\> <venv>\Scripts\Activate.ps1`

New in version 3.4: **!fish** and **!csh** activation scripts.

New in version 3.8: PowerShell activation scripts installed under POSIX for PowerShell Core support.

You don’t specifically *need* to activate a virtual environment, as you can just specify the full path to that environment’s Python interpreter when invoking Python. Furthermore, all scripts installed in the environment should be runnable without activating it.

In order to achieve this, scripts installed into virtual environments have a “shebang” line which points to the environment’s Python interpreter, i.e. `#!/<path-to-venv>/bin/python`. This means that the script will run with that interpreter regardless of the value of **PATH**. On Windows, “shebang” line processing is supported if you have the Python Launcher for Windows installed. Thus, double-clicking an installed script in a Windows Explorer window should run it with the correct interpreter without the environment needing to be activated or on the **PATH**.

When a virtual environment has been activated, the **VIRTUAL_ENV** environment variable is set to the path of the environment. Since

explicitly activating a virtual environment is not required to use it, **VIRTUAL_ENV** cannot be relied upon to determine whether a virtual environment is being used.

Warning

Because scripts installed in environments should not expect the environment to be activated, their shebang lines contain the absolute paths to their environment's interpreters. Because of this, environments are inherently non-portable, in the general case. You should always have a simple means of recreating an environment (for example, if you have a requirements file `requirements.txt`, you can invoke `pip install -r requirements.txt` using the environment's `pip` to install all of the packages needed by the environment). If for any reason you need to move the environment to a new location, you should recreate it at the desired location and delete the one at the old location. If you move an environment because you moved a parent directory of it, you should recreate the environment in its new location. Otherwise, software installed into the environment may not work as expected.

You can deactivate a virtual environment by typing `deactivate` in your shell. The exact mechanism is platform-specific and is an internal implementation detail (typically, a script or shell function will be used).

API

The high-level method described above makes use of a simple API which provides mechanisms for third-party virtual environment creators to customize environment creation according to their needs, the **EnvBuilder** class.

class venv.EnvBuilder(*system_site_packages=False*, *clear=False*, *symlinks=False*, *upgrade=False*, *with_pip=False*, *prompt=None*, *upgrade_deps=False*)

The **EnvBuilder** class accepts the following keyword

arguments on instantiation:

- `system_site_packages` – a Boolean value indicating that the system Python site-packages should be available to the environment (defaults to `False`).
- `clear` – a Boolean value which, if true, will delete the contents of any existing target directory, before creating the environment.
- `symlinks` – a Boolean value indicating whether to attempt to symlink the Python binary rather than copying.
- `upgrade` – a Boolean value which, if true, will upgrade an existing environment with the running Python - for use when that Python has been upgraded in-place (defaults to `False`).
- `with_pip` – a Boolean value which, if true, ensures pip is installed in the virtual environment. This uses **`ensurepip`** with the `--default-pip` option.
- `prompt` – a String to be used after virtual environment is activated (defaults to `None` which means directory name of the environment would be used). If the special string `"."` is provided, the basename of the current directory is used as the prompt.
- `upgrade_deps` – Update the base venv modules to the latest on PyPI

Changed in version 3.4: Added the `with_pip` parameter

New in version 3.6: Added the `prompt` parameter

New in version 3.9: Added the `upgrade_deps` parameter

Creators of third-party virtual environment tools will be free to use the provided **`EnvBuilder`** class as a base class.

The returned env-builder is an object which has a method, `create`:

create(*env_dir*)

Create a virtual environment by specifying the target directory (absolute or relative to the current directory)

which is to contain the virtual environment. The `create` method will either create the environment in the specified directory, or raise an appropriate exception.

The `create` method of the **`EnvBuilder`** class illustrates the hooks available for subclass customization:

```
def create(self, env_dir):
    """
    Create a virtualized Python environment in
    env_dir is the target directory to create a
    """
    env_dir = os.path.abspath(env_dir)
    context = self.ensure_directories(env_dir)
    self.create_configuration(context)
    self.setup_python(context)
    self.setup_scripts(context)
    self.post_setup(context)
```

Each of the methods **`ensure_directories()`**, **`create_configuration()`**, **`setup_python()`**, **`setup_scripts()`** and **`post_setup()`** can be overridden.

ensure_directories(*env_dir*)

Creates the environment directory and all necessary subdirectories that don't already exist, and returns a context object. This context object is just a holder for attributes (such as paths) for use by the other methods. If the **`EnvBuilder`** is created with the arg `clear=True`, contents of the environment directory will be cleared and then all necessary subdirectories will be recreated.

The returned context object is a **`types.SimpleNamespace`** with the following attributes:

- `env_dir` - The location of the virtual environment. Used for `__VENV_DIR__` in activation scripts (see **`install_scripts()`**).
- `env_name` - The name of the virtual environment. Used for `__VENV_NAME__` in activation scripts (see **`install_scripts()`**).
- `prompt` - The prompt to be used by the activation scripts. Used for `__VENV_PROMPT__` in activation scripts (see **`install_scripts()`**).
- `executable` - The underlying Python executable used by the virtual environment. This takes into account the case where a virtual environment is created from another virtual environment.
- `inc_path` - The include path for the virtual environment.
- `lib_path` - The purelib path for the virtual environment.
- `bin_path` - The script path for the virtual environment.
- `bin_name` - The name of the script path relative to the virtual environment location. Used for `__VENV_BIN_NAME__` in activation scripts (see **`install_scripts()`**).
- `env_exe` - The name of the Python interpreter in the virtual environment. Used for `__VENV_PYTHON__` in activation scripts (see **`install_scripts()`**).
- `env_exec_cmd` - The name of the Python interpreter, taking into account filesystem redirections. This can be used to run Python in the virtual environment.

Changed in version 3.12: The attribute `lib_path` was added to the context, and the context object was documented.

Changed in version 3.11: The *venv* sysconfig installation scheme is used to construct the paths of the created directories.

create_configuration(*context*)

Creates the `pyvenv.cfg` configuration file in the environment.

setup_python(*context*)

Creates a copy or symlink to the Python executable in the environment. On POSIX systems, if a specific executable `python3.x` was used, symlinks to `python` and `python3` will be created pointing to that executable, unless files with those names already exist.

setup_scripts(*context*)

Installs activation scripts appropriate to the platform into the virtual environment.

upgrade_dependencies(*context*)

Upgrades the core venv dependency packages (currently `pip` and `setuptools`) in the environment. This is done by shelling out to the `pip` executable in the environment.

New in version 3.9.

post_setup(*context*)

A placeholder method which can be overridden in third party implementations to pre-install packages in the virtual environment or perform other post-creation steps.

Changed in version 3.7.2: Windows now uses redirector scripts for `python[w].exe` instead of copying the actual binaries. In 3.7.2 only **`setup_python()`** does nothing unless running from a build in the source tree.

Changed in version 3.7.3: Windows copies the redirector scripts as part of **`setup_python()`** instead of **`setup_scripts()`**. This was not the case in 3.7.2. When

using symlinks, the original executables will be linked.

In addition, **EnvBuilder** provides this utility method that can be called from **setup_scripts()** or **post_setup()** in subclasses to assist in installing custom scripts into the virtual environment.

install_scripts(*context*, *path*)

path is the path to a directory that should contain subdirectories “common”, “posix”, “nt”, each containing scripts destined for the bin directory in the environment. The contents of “common” and the directory corresponding to **os.name** are copied after some text replacement of placeholders:

- `__VENV_DIR__` is replaced with the absolute path of the environment directory.
- `__VENV_NAME__` is replaced with the environment name (final path segment of environment directory).
- `__VENV_PROMPT__` is replaced with the prompt (the environment name surrounded by parentheses and with a following space)
- `__VENV_BIN_NAME__` is replaced with the name of the bin directory (either `bin` or `Scripts`).
- `__VENV_PYTHON__` is replaced with the absolute path of the environment’s executable.

The directories are allowed to exist (for when an existing environment is being upgraded).

There is also a module-level convenience function:

venv.create(*env_dir*, *system_site_packages*=*False*, *clear*=*False*, *symlinks*=*False*, *with_pip*=*False*, *prompt*=*None*, *upgrade_deps*=*False*)

Create an **EnvBuilder** with the given keyword arguments, and call its **create()** method with the *env_dir* argument.

New in version 3.3.

Changed in version 3.4: Added the `with_pip` parameter

Changed in version 3.6: Added the `prompt` parameter

Changed in version 3.9: Added the `upgrade_deps` parameter

An example of extending `EnvBuilder`

The following script shows how to extend **`EnvBuilder`** by implementing a subclass which installs setuptools and pip into a created virtual environment:

```
import os
import os.path
from subprocess import Popen, PIPE
import sys
from threading import Thread
from urllib.parse import urlparse
from urllib.request import urlretrieve
import venv

class ExtendedEnvBuilder(venv.EnvBuilder):
    """
    This builder installs setuptools and pip so that you
    easy_install other packages into the created virtual

    :param nodist: If true, setuptools and pip are not i
                   created virtual environment.
    :param nopip: If true, pip is not installed into the
                  virtual environment.
    :param progress: If setuptools or pip are installed,
                     installation can be monitored by pa
                     callable. If specified, it is calle
                     arguments: a string indicating some
                     context indicating where the string
                     The context argument can have one o
                     'main', indicating that it is calle
                     itself, and 'stdout' and 'stderr',
                     by reading lines from the output st
```

```
                    which is used to install the app.

                    If a callable is not specified, def
                    information is output to sys.stderr
    """

    def __init__(self, *args, **kwargs):
        self.nodist = kwargs.pop('nodist', False)
        self.nopip = kwargs.pop('nopip', False)
        self.progress = kwargs.pop('progress', None)
        self.verbose = kwargs.pop('verbose', False)
        super().__init__(*args, **kwargs)

    def post_setup(self, context):
        """
        Set up any packages which need to be pre-install
        virtual environment being created.

`zipapp` — Manage executable Python zip archives

New in version 3.5.

Source code: Lib/zipapp.py [https://github.com/python/cpython/tree/3.11/Lib/zipapp.py]

This module provides tools to manage the creation of zip files containing Python code, which can be executed directly by the Python interpreter. The module provides both a Command-Line Interface and a Python API.

Basic Example

The following example shows how the Command-Line Interface can be used to create an executable archive from a directory containing Python code. When run, the archive will execute the `main` function from the module `myapp` in the archive.

```
$ python -m zipapp myapp -m "myapp:main"
$ python myapp.pyz
<output from myapp>
```

Command-Line Interface

When called as a program from the command line, the following form is used:

```
$ python -m zipapp source [options]
```

If *source* is a directory, this will create an archive from the contents of *source*. If *source* is a file, it should be an archive, and it will be copied to the target archive (or the contents of its shebang line will

be displayed if the –info option is specified).

The following options are understood:

-o <output>, --output=<output>

Write the output to a file named *output*. If this option is not specified, the output filename will be the same as the input *source*, with the extension `.pyz` added. If an explicit filename is given, it is used as is (so a `.pyz` extension should be included if required).

An output filename must be specified if the *source* is an archive (and in that case, *output* must not be the same as *source*).

-p <interpreter>, --python=<interpreter>

Add a `#!` line to the archive specifying *interpreter* as the command to run. Also, on POSIX, make the archive executable. The default is to write no `#!` line, and not make the file executable.

-m <mainfn>, --main=<mainfn>

Write a `__main__.py` file to the archive that executes *mainfn*. The *mainfn* argument should have the form "pkg.mod:fn", where "pkg.mod" is a package/module in the archive, and "fn" is a callable in the given module. The `__main__.py` file will execute that callable.

`--main` cannot be specified when copying an archive.

-c, --compress

Compress files with the deflate method, reducing the size of the output file. By default, files are stored uncompressed in the archive.

`--compress` has no effect when copying an archive.

New in version 3.7.

--info

Display the interpreter embedded in the archive, for diagnostic purposes. In this case, any other options are ignored and SOURCE must be an archive, not a directory.

-h, --help

Print a short usage message and exit.

Python API

The module defines two convenience functions:

zipapp.create_archive(*source*, *target=None*, *interpreter=None*, *main=None*, *filter=None*, *compressed=False*)

Create an application archive from *source*. The source can be any of the following:

- The name of a directory, or a path-like object referring to a directory, in which case a new application archive will be created from the content of that directory.
- The name of an existing application archive file, or a path-like object referring to such a file, in which case the file is copied to the target (modifying it to reflect the value given for the *interpreter* argument). The file name should include the `.pyz` extension, if required.
- A file object open for reading in bytes mode. The content of the file should be an application archive, and the file object is assumed to be positioned at the start of the archive.

The *target* argument determines where the resulting archive will be written:

- If it is the name of a file, or a path-like object, the archive will be written to that file.
- If it is an open file object, the archive will be written to that file object, which must be open for writing in bytes mode.
- If the target is omitted (or `None`), the source must be a

directory and the target will be a file with the same name as the source, with a `.pyz` extension added.

The *interpreter* argument specifies the name of the Python interpreter with which the archive will be executed. It is written as a "shebang" line at the start of the archive. On POSIX, this will be interpreted by the OS, and on Windows it will be handled by the Python launcher. Omitting the *interpreter* results in no shebang line being written. If an interpreter is specified, and the target is a filename, the executable bit of the target file will be set.

The *main* argument specifies the name of a callable which will be used as the main program for the archive. It can only be specified if the source is a directory, and the source does not already contain a `__main__.py` file. The *main* argument should take the form "pkg.module:callable" and the archive will be run by importing "pkg.module" and executing the given callable with no arguments. It is an error to omit *main* if the source is a directory and does not contain a `__main__.py` file, as otherwise the resulting archive would not be executable.

The optional *filter* argument specifies a callback function that is passed a Path object representing the path to the file being added (relative to the source directory). It should return `True` if the file is to be added.

The optional *compressed* argument determines whether files are compressed. If set to `True`, files in the archive are compressed with the deflate method; otherwise, files are stored uncompressed. This argument has no effect when copying an existing archive.

If a file object is specified for *source* or *target*, it is the caller's responsibility to close it after calling create_archive.

When copying an existing archive, file objects supplied only need `read` and `readline`, or `write` methods. When creating an archive from a directory, if the target is a file object it will be passed to the `zipfile.ZipFile` class, and

must supply the methods needed by that class.

New in version 3.7: Added the *filter* and *compressed* arguments.

zipapp.get_interpreter(*archive*)

Return the interpreter specified in the `#!` line at the start of the archive. If there is no `#!` line, return **`None`**. The *archive* argument can be a filename or a file-like object open for reading in bytes mode. It is assumed to be at the start of the archive.

Examples

Pack up a directory into an archive, and run it.

```
$ python -m zipapp myapp
$ python myapp.pyz
<output from myapp>
```

The same can be done using the **`create_archive()`** function:

```
>>> import zipapp
>>> zipapp.create_archive('myapp', 'myapp.pyz')
```

To make the application directly executable on POSIX, specify an interpreter to use.

```
$ python -m zipapp myapp -p "/usr/bin/env python"
$ ./myapp.pyz
<output from myapp>
```

To replace the shebang line on an existing archive, create a modified archive using the **`create_archive()`** function:

```
>>> import zipapp
>>> zipapp.create_archive('old_archive.pyz', 'new_archiv
```

To update the file in place, do the replacement in memory using a **`BytesIO`** object, and then overwrite the source afterwards. Note that there is a risk when overwriting a file in place that an error

will result in the loss of the original file. This code does not protect against such errors, but production code should do so. Also, this method will only work if the archive fits in memory:

```
>>> import zipapp
>>> import io
>>> temp = io.BytesIO()
>>> zipapp.create_archive('myapp.pyz', temp, '/usr/bin/p
>>> with open('myapp.pyz', 'wb') as f:
>>>     f.write(temp.getvalue())
```

Specifying the Interpreter

Note that if you specify an interpreter and then distribute your application archive, you need to ensure that the interpreter used is portable. The Python launcher for Windows supports most common forms of POSIX `#!` line, but there are other issues to consider:

- If you use "/usr/bin/env python" (or other forms of the "python" command, such as "/usr/bin/python"), you need to consider that your users may have either Python 2 or Python 3 as their default, and write your code to work under both versions.
- If you use an explicit version, for example "/usr/bin/env python3" your application will not work for users who do not have that version. (This may be what you want if you have not made your code Python 2 compatible).
- There is no way to say "python X.Y or later", so be careful of using an exact version like "/usr/bin/env python3.4" as you will need to change your shebang line for users of Python 3.5, for example.

Typically, you should use an "/usr/bin/env python2" or "/usr/bin/env python3", depending on whether your code is written for Python 2 or 3.

Creating Standalone Applications with zipapp

Using the **zipapp** module, it is possible to create self-contained Python programs, which can be distributed to end users who only need to have a suitable version of Python installed on their system. The key to doing this is to bundle all of the application's dependencies into the archive, along with the application code.

The steps to create a standalone archive are as follows:

1. Create your application in a directory as normal, so you have a `myapp` directory containing a `__main__.py` file, and any supporting application code.

2. Install all of your application's dependencies into the `myapp` directory, using pip:

   ```
   $ python -m pip install -r requirements.txt --targe
   ```

   (this assumes you have your project requirements in a `requirements.txt` file - if not, you can just list the dependencies manually on the pip command line).

3. Optionally, delete the `.dist-info` directories created by pip in the `myapp` directory. These hold metadata for pip to manage the packages, and as you won't be making any further use of pip they aren't required - although it won't do any harm if you leave them.

4. Package the application using:

   ```
   $ python -m zipapp -p "interpreter" myapp
   ```

This will produce a standalone executable, which can be run on any machine with the appropriate interpreter available. See Specifying the Interpreter for details. It can be shipped to users as a single file.

On Unix, the `myapp.pyz` file is executable as it stands. You can rename the file to remove the `.pyz` extension if you prefer a "plain" command name. On Windows, the `myapp.pyz[w]` file is executable by virtue of the fact that the Python interpreter registers the `.pyz` and `.pyzw` file extensions when installed.

Making a Windows executable

On Windows, registration of the `.pyz` extension is optional, and furthermore, there are certain places that don't recognise registered extensions "transparently" (the simplest example is that `subprocess.run(['myapp'])` won't find your application - you need to explicitly specify the extension).

On Windows, therefore, it is often preferable to create an executable from the zipapp. This is relatively easy, although it does require a C compiler. The basic approach relies on the fact that zipfiles can have arbitrary data prepended, and Windows exe files can have arbitrary data appended. So by creating a suitable launcher and tacking the `.pyz` file onto the end of it, you end up with a single-file executable that runs your application.

A suitable launcher can be as simple as the following:

```
#define Py_LIMITED_API 1
#include "Python.h"

#define WIN32_LEAN_AND_MEAN
#include <windows.h>

#ifdef WINDOWS
int WINAPI wWinMain(
    HINSTANCE hInstance,      /* handle to current insta
    HINSTANCE hPrevInstance,  /* handle to previous inst
    LPWSTR lpCmdLine,         /* pointer to command line
    int nCmdShow              /* show state of window */
)
#else
int wmain()
#endif
{
    wchar_t **myargv = _alloca((__argc + 1) * sizeof(wch
    myargv[0] = __wargv[0];
    memcpy(myargv + 1, __wargv, __argc * sizeof(wchar_t
    return Py_Main(__argc+1, myargv);
```

```
}
```

If you define the `WINDOWS` preprocessor symbol, this will generate a GUI executable, and without it, a console executable.

To compile the executable, you can either just use the standard MSVC command line tools, or you can take advantage of the fact that distutils knows how to compile Python source:

```
>>> from distutils.ccompiler import new_compiler
>>> import distutils.sysconfig
>>> import sys
>>> import os
>>> from pathlib import Path

>>> def compile(src):
>>>     src = Path(src)
>>>     cc = new_compiler()
>>>     exe = src.stem
>>>     cc.add_include_dir(distutils.sysconfig.get_pytho
>>>     cc.add_library_dir(os.path.join(sys.base_exec_pr
>>>     # First the CLI executable
>>>     objs = cc.compile([str(src)])
>>>     cc.link_executable(objs, exe)
>>>     # Now the GUI executable
>>>     cc.define_macro('WINDOWS')
>>>     objs = cc.compile([str(src)])
>>>     cc.link_executable(objs, exe + 'w')

>>> if __name__ == "__main__":
>>>     compile("zastub.c")
```

The resulting launcher uses the “Limited ABI”, so it will run unchanged with any version of Python 3.x. All it needs is for Python (`python3.dll`) to be on the user’s `PATH`.

For a fully standalone distribution, you can distribute the launcher with your application appended, bundled with the Python “embedded” distribution. This will run on any PC with the appropriate architecture (32 bit or 64 bit).

Caveats

There are some limitations to the process of bundling your application into a single file. In most, if not all, cases they can be addressed without needing major changes to your application.

1. If your application depends on a package that includes a C extension, that package cannot be run from a zip file (this is an OS limitation, as executable code must be present in the filesystem for the OS loader to load it). In this case, you can exclude that dependency from the zipfile, and either require your users to have it installed, or ship it alongside your zipfile and add code to your `__main__.py` to include the directory containing the unzipped module in `sys.path`. In this case, you will need to make sure to ship appropriate binaries for your target architecture(s) (and potentially pick the correct version to add to `sys.path` at runtime, based on the user's machine).
2. If you are shipping a Windows executable as described above, you either need to ensure that your users have `python3.dll` on their PATH (which is not the default behaviour of the installer) or you should bundle your application with the embedded distribution.
3. The suggested launcher above uses the Python embedding API. This means that in your application, `sys.executable` will be your application, and *not* a conventional Python interpreter. Your code and its dependencies need to be prepared for this possibility. For example, if your application uses the **`multiprocessing`** module, it will need to call **`multiprocessing.set_executable()`** to let the module know where to find the standard Python interpreter.

The Python Zip Application Archive Format

Python has been able to execute zip files which contain a `__main__.py` file since version 2.6. In order to be executed by Python, an application archive simply has to be a standard zip file containing a `__main__.py` file which will be run as the entry

point for the application. As usual for any Python script, the parent of the script (in this case the zip file) will be placed on **`sys.path`** and thus further modules can be imported from the zip file.

The zip file format allows arbitrary data to be prepended to a zip file. The zip application format uses this ability to prepend a standard POSIX "shebang" line to the file (`#!/path/to/interpreter`).

Formally, the Python zip application format is therefore:

1. An optional shebang line, containing the characters `b'#!'` followed by an interpreter name, and then a newline (`b'\n'`) character. The interpreter name can be anything acceptable to the OS "shebang" processing, or the Python launcher on Windows. The interpreter should be encoded in UTF-8 on Windows, and in **`sys.getfilesystemencoding()`** on POSIX.
2. Standard zipfile data, as generated by the **`zipfile`** module. The zipfile content *must* include a file called `__main__.py` (which must be in the "root" of the zipfile - i.e., it cannot be in a subdirectory). The zipfile data can be compressed or uncompressed.

If an application archive has a shebang line, it may have the executable bit set on POSIX systems, to allow it to be executed directly.

There is no requirement that the tools in this module are used to create application archives - the module is a convenience, but archives in the above format created by any means are acceptable to Python.

Python Runtime Services

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here's an overview:

- **sys** — System-specific parameters and functions
- **sysconfig** — Provide access to Python's configuration information
  - Configuration variables
  - Installation paths
  - Other functions
  - Using **sysconfig** as a script
- **builtins** — Built-in objects
- **__main__** — Top-level code environment
  - **__name__ == '__main__'**
    - What is the "top-level code environment"?
    - Idiomatic Usage
    - Packaging Considerations
  - **__main__.py** in Python Packages
    - Idiomatic Usage
  - **import __main__**
- **warnings** — Warning control
  - Warning Categories
  - The Warnings Filter
    - Describing Warning Filters
    - Default Warning Filter
    - Overriding the default filter

    - Temporarily Suppressing Warnings
    - Testing Warnings
    - Updating Code For New Versions of Dependencies
    - Available Functions
    - Available Context Managers

- **dataclasses** — Data Classes

    - Module contents
    - Post-init processing
    - Class variables
    - Init-only variables
    - Frozen instances
    - Inheritance
    - Re-ordering of keyword-only parameters in **__init__()**
    - Default factory functions
    - Mutable default values
    - Descriptor-typed fields

- **contextlib** — Utilities for **with**-statement contexts

    - Utilities
    - Examples and Recipes

        - Supporting a variable number of context managers
        - Catching exceptions from **__enter__** methods
        - Cleaning up in an **__enter__** implementation
        - Replacing any use of **try-finally** and flag variables
        - Using a context manager as a function decorator

    - Single use, reusable and reentrant context managers

        - Reentrant context managers
        - Reusable context managers

- **abc** — Abstract Base Classes
- **atexit** — Exit handlers

    - **atexit** Example

- **traceback** — Print or retrieve a stack traceback

    - **TracebackException** Objects
    - **StackSummary** Objects
    - **FrameSummary** Objects
    - Traceback Examples

- **__future__** — Future statement definitions
- **gc** — Garbage Collector interface
- **inspect** — Inspect live objects

    - Types and members
    - Retrieving source code
    - Introspecting callables with the Signature object
    - Classes and functions
    - The interpreter stack
    - Fetching attributes statically
    - Current State of Generators and Coroutines
    - Code Objects Bit Flags
    - Command Line Interface

- **site** — Site-specific configuration hook

    - Readline configuration
    - Module contents
    - Command Line Interface

`sys` — System-specific parameters and functions

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available.

sys.abiflags

On POSIX systems where Python was built with the standard `configure` script, this contains the ABI flags as specified by **PEP 3149** [https://peps.python.org/pep-3149/].

Changed in version 3.8: Default flags became an empty string (`m` flag for pymalloc has been removed).

New in version 3.2.

sys.addaudithook(*hook*)

Append the callable *hook* to the list of active auditing hooks for the current (sub)interpreter.

When an auditing event is raised through the **`sys.audit()`** function, each hook will be called in the order it was added with the event name and the tuple of arguments. Native hooks added by **`PySys_AddAuditHook()`** are called first, followed by hooks added in the current (sub)interpreter. Hooks can then log the event, raise an exception to abort the operation, or terminate the process entirely.

Note that audit hooks are primarily for collecting information about internal or otherwise unobservable actions, whether by Python or libraries written in Python. They are not suitable for implementing a “sandbox”. In particular, malicious code can trivially disable or bypass hooks added using this

function. At a minimum, any security-sensitive hooks must be added using the C API **PySys_AddAuditHook()** before initialising the runtime, and any modules allowing arbitrary memory modification (such as **ctypes**) should be completely removed or closely monitored.

Calling **sys.addaudithook()** will itself raise an auditing event named `sys.addaudithook` with no arguments. If any existing hooks raise an exception derived from **RuntimeError**, the new hook will not be added and the exception suppressed. As a result, callers cannot assume that their hook has been added unless they control all existing hooks.

See the audit events table for all events raised by CPython, and **PEP 578** [https://peps.python.org/pep-0578/] for the original design discussion.

New in version 3.8.

Changed in version 3.8.1: Exceptions derived from **Exception** but not **RuntimeError** are no longer suppressed.

CPython implementation detail: When tracing is enabled (see **settrace()**), Python hooks are only traced if the callable has a `__cantrace__` member that is set to a true value. Otherwise, trace functions will skip the hook.

sys.argv

The list of command line arguments passed to a Python script. `argv[0]` is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the **-c** command line option to the interpreter, `argv[0]` is set to the string `'-c'`. If no script name was passed to the Python interpreter, `argv[0]` is the empty string.

To loop over the standard input, or the list of files given on

the command line, see the **fileinput** module.

See also **sys.orig_argv**.

Note

On Unix, command line arguments are passed by bytes from OS. Python decodes them with filesystem encoding and "surrogateescape" error handler. When you need original bytes, you can get it by `[os.fsencode(arg) for arg in sys.argv]`.

sys.audit(*event*, **args*)

Raise an auditing event and trigger any active auditing hooks. *event* is a string identifying the event, and *args* may contain optional arguments with more information about the event. The number and types of arguments for a given event are considered a public and stable API and should not be modified between releases.

For example, one auditing event is named `os.chdir`. This event has one argument called *path* that will contain the requested new working directory.

sys.audit() will call the existing auditing hooks, passing the event name and arguments, and will re-raise the first exception from any hook. In general, if an exception is raised, it should not be handled and the process should be terminated as quickly as possible. This allows hook implementations to decide how to respond to particular events: they can merely log the event or abort the operation by raising an exception.

Hooks are added using the **sys.addaudithook()** or **PySys_AddAuditHook()** functions.

The native equivalent of this function is **PySys_Audit()**. Using the native function is preferred when possible.

See the audit events table for all events raised by CPython.

New in version 3.8.

sys.base_exec_prefix

Set during Python startup, before `site.py` is run, to the same value as **`exec_prefix`**. If not running in a virtual environment, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of **`prefix`** and **`exec_prefix`** will be changed to point to the virtual environment, whereas **`base_prefix`** and **`base_exec_prefix`** will remain pointing to the base Python installation (the one which the virtual environment was created from).

New in version 3.3.

sys.base_prefix

Set during Python startup, before `site.py` is run, to the same value as **`prefix`**. If not running in a virtual environment, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of **`prefix`** and **`exec_prefix`** will be changed to point to the virtual environment, whereas **`base_prefix`** and **`base_exec_prefix`** will remain pointing to the base Python installation (the one which the virtual environment was created from).

New in version 3.3.

sys.byteorder

An indicator of the native byte order. This will have the value `'big'` on big-endian (most-significant byte first) platforms, and `'little'` on little-endian (least-significant byte first) platforms.

sys.builtin_module_names

A tuple of strings containing the names of all modules that are compiled into this Python interpreter. (This information is

not available in any other way — `modules.keys()` only lists the imported modules.)

See also the **`sys.stdlib_module_names`** list.

sys.call_tracing(*func*, *args*)

Call `func(*args)`, while tracing is enabled. The tracing state is saved, and restored afterwards. This is intended to be called from a debugger from a checkpoint, to recursively debug some other code.

sys.copyright

A string containing the copyright pertaining to the Python interpreter.

sys._clear_type_cache()

Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function *only* to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

sys._current_frames()

Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the **`traceback`** module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

Raises an auditing event `sys._current_frames` with no arguments.

sys._current_exceptions()

Return a dictionary mapping each thread's identifier to the topmost exception currently active in that thread at the time the function is called. If a thread is not currently handling an exception, it is not included in the result dictionary.

This is most useful for statistical profiling.

This function should be used for internal and specialized purposes only.

Raises an auditing event `sys._current_exceptions` with no arguments.

sys.breakpointhook()

This hook function is called by built-in **`breakpoint()`**. By default, it drops you into the **`pdb`** debugger, but it can be set to any other function so that you can choose which debugger gets used.

The signature of this function is dependent on what it calls. For example, the default binding (e.g. `pdb.set_trace()`) expects no arguments, but you might bind it to a function that expects additional arguments (positional and/or keyword). The built-in `breakpoint()` function passes its `*args` and `**kws` straight through. Whatever `breakpointhooks()` returns is returned from `breakpoint()`.

The default implementation first consults the environment variable **`PYTHONBREAKPOINT`**. If that is set to `"0"` then this function returns immediately; i.e. it is a no-op. If the environment variable is not set, or is set to the empty string, `pdb.set_trace()` is called. Otherwise this variable should name a function to run, using Python's dotted-import nomenclature, e.g. `package.subpackage.module.function`. In this case,

`package.subpackage.module` would be imported and the resulting module must have a callable named `function()`. This is run, passing in `*args` and `**kws`, and whatever `function()` returns, `sys.breakpointhook()` returns to the built-in **`breakpoint()`** function.

Note that if anything goes wrong while importing the callable named by **`PYTHONBREAKPOINT`**, a **`RuntimeWarning`** is reported and the breakpoint is ignored.

Also note that if `sys.breakpointhook()` is overridden programmatically, **`PYTHONBREAKPOINT`** is *not* consulted.

New in version 3.7.

sys._debugmallocstats()

Print low-level information to stderr about the state of CPython's memory allocator.

If Python is built in debug mode (**`configure --with-pydebug option`**), it also performs some expensive internal consistency checks.

New in version 3.3.

CPython implementation detail: This function is specific to CPython. The exact output format is not defined here, and may change.

sys.dllhandle

Integer specifying the handle of the Python DLL.

Availability: Windows.

sys.displayhook(*value*)

If *value* is not `None`, this function prints `repr(value)` to `sys.stdout`, and saves *value* in `builtins._`. If `repr(value)` is not encodable to `sys.stdout.encoding` with `sys.stdout.errors` error handler (which is probably `'strict'`), encode it to `sys.stdout.encoding` with

`'backslashreplace'` error handler.

`sys.displayhook` is called on the result of evaluating an expression entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

Pseudo-code:

```
def displayhook(value):
    if value is None:
        return
    # Set '_' to None to avoid recursion
    builtins._ = None
    text = repr(value)
    try:
        sys.stdout.write(text)
    except UnicodeEncodeError:
        bytes = text.encode(sys.stdout.encoding, 'b
        if hasattr(sys.stdout, 'buffer'):
            sys.stdout.buffer.write(bytes)
        else:
            text = bytes.decode(sys.stdout.encoding
            sys.stdout.write(text)
    sys.stdout.write("\n")
    builtins._ = value
```

Changed in version 3.2: Use `'backslashreplace'` error handler on **`UnicodeEncodeError`**.

sys.dont_write_bytecode

If this is true, Python won't try to write `.pyc` files on the import of source modules. This value is initially set to `True` or `False` depending on the **`-B`** command line option and the **`PYTHONDONTWRITEBYTECODE`** environment variable, but you can set it yourself to control bytecode file generation.

sys._emscripten_info

A named tuple holding information about the environment on

the *wasm32-emscripten* platform. The named tuple is provisional and may change in the future.

Attribute	Explanation
emscripten_version	Emscripten version, a tuple of ints (major, minor, micro), e.g. `(3, 1, 8)`.
runtime	Runtime string, e.g. browser user agent, `'Node.js v14.18.2'`, or `'UNKNOWN'`.
pthreads	`True` if Python is compiled with Emscripten pthreads support.
shared_memory	`True` if Python is compiled with shared memory support.

Availability: Emscripten.

New in version 3.11.

sys.pycache_prefix

If this is set (not `None`), Python will write bytecode-cache `.pyc` files to (and read them from) a parallel directory tree rooted at this directory, rather than from `__pycache__` directories in the source code tree. Any `__pycache__` directories in the source code tree will be ignored and new `.pyc` files written within the pycache prefix. Thus if you use **`compileall`** as a pre-build step, you must ensure you run it with the same pycache prefix (if any) that you will use at runtime.

A relative path is interpreted relative to the current working directory.

This value is initially set based on the value of the **`-X`** `pycache_prefix=PATH` command-line option or the **`PYTHONPYCACHEPREFIX`** environment variable (command-line takes precedence). If neither are set, it is `None`.

New in version 3.8.

sys.excepthook(*type*, *value*, *traceback*)

This function prints out a given traceback and exception to `sys.stderr`.

When an exception is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

Raise an auditing event `sys.excepthook` with arguments `hook`, `type`, `value`, `traceback` when an uncaught exception occurs. If no hook has been set, `hook` may be `None`. If any hook raises an exception derived from **`RuntimeError`** the call to the hook will be suppressed. Otherwise, the audit hook exception will be reported as unraisable and `sys.excepthook` will be called.

See also

The **`sys.unraisablehook()`** function handles unraisable exceptions and the **`threading.excepthook()`** function handles exception raised by **`threading.Thread.run()`**.

sys._breakpointhook_
sys._displayhook_
sys._excepthook_
sys._unraisablehook_

These objects contain the original values of `breakpointhook`, `displayhook`, `excepthook`, and `unraisablehook` at the start of the program. They are saved so that `breakpointhook`, `displayhook` and `excepthook`, `unraisablehook` can be restored in case they happen to get replaced with broken or alternative objects.

New in version 3.7: _breakpointhook_

New in version 3.8: _unraisablehook_

sys.exception()

This function, when called while an exception handler is executing (such as an `except` or `except*` clause), returns the exception instance that was caught by this handler. When exception handlers are nested within one another, only the exception handled by the innermost handler is accessible.

If no exception handler is executing, this function returns `None`.

New in version 3.11.

sys.exc_info()

This function returns the old-style representation of the handled exception. If an exception `e` is currently handled (so **`exception()`** would return `e`), **`exc_info()`** returns the tuple `(type(e), e, e.__traceback__)`. That is, a tuple containing the type of the exception (a subclass of **`BaseException`**), the exception itself, and a traceback object which typically encapsulates the call stack at the point where the exception last occurred.

If no exception is being handled anywhere on the stack, this function return a tuple containing three `None` values.

Changed in version 3.11: The `type` and `traceback` fields are now derived from the `value` (the exception instance), so when an exception is modified while it is being handled, the changes are reflected in the results of subsequent calls to **`exc_info()`**.

sys.exec_prefix

A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `'/usr/local'`. This can be set at build time with the `--exec-prefix` argument to the **configure** script. Specifically, all configuration files (e.g. the `pyconfig.h`

header file) are installed in the directory *exec_prefix*`/lib/python`*X.Y*`/config`, and shared library modules are installed in *exec_prefix*`/lib/python`*X.Y*`/lib-dynload`, where *X.Y* is the version number of Python, for example `3.2`.

Note

If a virtual environment is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via **`base_exec_prefix`**.

sys.executable

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes sense. If Python is unable to retrieve the real path to its executable, **`sys.executable`** will be an empty string or `None`.

sys.exit([*arg*])

Raise a **`SystemExit`** exception, signaling an intention to exit the interpreter.

The optional argument *arg* can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered “successful termination” and any nonzero value is considered “abnormal termination” by shells and the like. Most systems require it to be in the range 0–127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all other kind of errors. If another type of object is passed, `None` is equivalent to passing zero, and any other object is printed to **`stderr`** and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since `exit()` ultimately "only" raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted. Cleanup actions specified by finally clauses of `try` statements are honored, and it is possible to intercept the exit attempt at an outer level.

Changed in version 3.6: If an error occurs in the cleanup after the Python interpreter has caught `SystemExit` (such as an error flushing buffered data in the standard streams), the exit status is changed to 120.

sys.flags

The named tuple *flags* exposes the status of command line flags. The attributes are read only.

attribute	flag
`debug`	`-d`
`inspect`	`-i`
`interactive`	`-i`
`isolated`	`-I`
`optimize`	`-O` or `-OO`
`dont_write_bytecode`	`-B`
`no_user_site`	`-s`
`no_site`	`-S`
`ignore_environment`	`-E`
`verbose`	`-v`
`bytes_warning`	`-b`
`quiet`	`-q`
`hash_randomization`	`-R`
`dev_mode`	`-X dev` (Python Development Mode)
`utf8_mode`	`-X utf8`
`safe_path`	`-P`
`int_max_str_digits`	`-X int_max_str_digits` (integer string conversion length limitation)

Changed in version 3.2: Added `quiet` attribute for the new `-q` flag.

New in version 3.2.3: The `hash_randomization` attribute.

Changed in version 3.3: Removed obsolete `division_warning` attribute.

Changed in version 3.4: Added `isolated` attribute for **`-I`** `isolated` flag.

Changed in version 3.7: Added the `dev_mode` attribute for the new Python Development Mode and the `utf8_mode` attribute for the new **`-X`** `utf8` flag.

Changed in version 3.11: Added the `safe_path` attribute for **`-P`** option.

Changed in version 3.11: Added the `int_max_str_digits` attribute.

sys.float_info

A named tuple holding information about the float type. It contains low level information about the precision and internal representation. The values correspond to the various floating-point constants defined in the standard header file `float.h` for the 'C' programming language; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [C99], 'Characteristics of floating types', for details.

attribute	float.h macro	meaning
epsilon	DBL_EPSILON	difference between 1.0 and the least value greater than 1.0 that is representable as a float See also **`math.ulp()`**.
dig	DBL_DIG	maximum number of decimal digits that can be faithfully represented in a float; see below
mant_dig	DBL_MANT_DIG	the number of base-`radix` digits in the significand of a float
max	DBL_MAX	maximum representable positive finite float
max_exp	DBL_MAX_EXP	maximum integer *e* such that `radix**(e-1)` is a representable finite float
max_10_exp	DBL_MAX_10_EXP	maximum integer *e* such that `10**e` is in the range of representable finite floats
min	DBL_MIN	minimum representable positive *normalized* float Use **`math.ulp(0.0)`** to get the smallest positive

denormalized representable float.

DBL_MIN_EXP integer *e* such that `radix**(e-1)` is a normalized float

DBL_MIN_10_EXP integer *e* such that `10**e` is a normalized float

RADIX exponent representation

FLT_ROUNDS constant representing the rounding mode used for arithmetic operations. This reflects the value of the system FLT_ROUNDS macro at interpreter startup time. See section 5.2.4.2.2 of the C99 standard for an explanation of the possible values and their meanings.

The attribute **`sys.float_info.dig`** needs further explanation. If `s` is any string representing a decimal number with at most **`sys.float_info.dig`** significant digits, then converting `s` to a float and back again will recover a string representing the same decimal value:

```
>>> import sys
>>> sys.float_info.dig
15
>>> s = '3.14159265358979'    # decimal string with
>>> format(float(s), '.15g')  # convert to float an
'3.14159265358979'
```

But for strings with more than **`sys.float_info.dig`** significant digits, this isn't always true:

```
>>> s = '9876543211234567'    # 16 significant digi
>>> format(float(s), '.16g')  # conversion changes
'9876543211234568'
```

sys.float_repr_style

A string indicating how the **`repr()`** function behaves for floats. If the string has value `'short'` then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 3.1 and later. Otherwise, `float_repr_style` has value `'legacy'` and `repr(x)` behaves in the same way as it did in versions of Python prior to 3.1.

New in version 3.1.

sys.getallocatedblocks()

Return the number of memory blocks currently allocated by the interpreter, regardless of their size. This function is mainly useful for tracking and debugging memory leaks. Because of the interpreter's internal caches, the result can vary from call to call; you may have to call **`_clear_type_cache()`** and **`gc.collect()`** to get more predictable results.

If a Python build or implementation cannot reasonably compute this information, **`getallocatedblocks()`** is allowed to return 0 instead.

New in version 3.4.

sys.getandroidapilevel()

Return the build time API version of Android as an integer.

Availability: Android.

New in version 3.7.

sys.getdefaultencoding()

Return the name of the current default string encoding used by the Unicode implementation.

sys.getdlopenflags()

Return the current value of the flags that are used for **`dlopen()`** calls. Symbolic names for the flag values can be found in the **`os`** module (`RTLD_xxx` constants, e.g. **`os.RTLD_LAZY`**).

Availability: Unix.

sys.getfilesystemencoding()

Get the filesystem encoding: the encoding used with the

filesystem error handler to convert between Unicode filenames and bytes filenames. The filesystem error handler is returned from **getfilesystemencoding()**.

For best compatibility, str should be used for filenames in all cases, although representing filenames as bytes is also supported. Functions accepting or returning filenames should support either str or bytes and internally convert to the system's preferred representation.

os.fsencode() and **os.fsdecode()** should be used to ensure that the correct encoding and errors mode are used.

The filesystem encoding and error handler are configured at Python startup by the **PyConfig_Read()** function: see **filesystem_encoding** and **filesystem_errors** members of **PyConfig**.

Changed in version 3.2: **getfilesystemencoding()** result cannot be `None` anymore.

Changed in version 3.6: Windows is no longer guaranteed to return `'mbcs'`. See **PEP 529** [https://peps.python.org/pep-0529/] and **_enablelegacywindowsfsencoding()** for more information.

Changed in version 3.7: Return `'utf-8'` if the Python UTF-8 Mode is enabled.

sys.getfilesystemencodeerrors()

Get the filesystem error handler: the error handler used with the filesystem encoding to convert between Unicode filenames and bytes filenames. The filesystem encoding is returned from **getfilesystemencoding()**.

os.fsencode() and **os.fsdecode()** should be used to ensure that the correct encoding and errors mode are used.

The filesystem encoding and error handler are configured at Python startup by the **PyConfig_Read()** function: see **filesystem_encoding** and **filesystem_errors**

members of **PyConfig**.

New in version 3.6.

sys.get_int_max_str_digits()

Returns the current value for the integer string conversion length limitation. See also **set_int_max_str_digits()**.

New in version 3.11.

sys.getrefcount(*object*)

Return the reference count of the *object*. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to **getrefcount()**.

sys.getrecursionlimit()

Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by **setrecursionlimit()**.

sys.getsizeof(*object*[, *default*])

Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

Only the memory consumption directly attributed to the object is accounted for, not the memory consumption of objects it refers to.

If given, *default* will be returned if the object does not provide means to retrieve the size. Otherwise a **TypeError** will be raised.

getsizeof() calls the object's `__sizeof__` method and adds an additional garbage collector overhead if the object is

managed by the garbage collector.

See recursive sizeof recipe [https://code.activestate.com/recipes/577504] for an example of using **`getsizeof()`** recursively to find the size of containers and all their contents.

sys.getswitchinterval()

Return the interpreter's "thread switch interval"; see **`setswitchinterval()`**.

New in version 3.2.

sys._getframe([*depth*])

Return a frame object from the call stack. If optional integer *depth* is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, **`ValueError`** is raised. The default for *depth* is zero, returning the frame at the top of the call stack.

Raises an auditing event `sys._getframe` with argument `frame`.

CPython implementation detail: This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

sys.getprofile()

Get the profiler function as set by **`setprofile()`**.

sys.gettrace()

Get the trace function as set by **`settrace()`**.

CPython implementation detail: The **`gettrace()`** function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python

implementations.

sys.getwindowsversion()

Return a named tuple describing the Windows version currently running. The named elements are *major*, *minor*, *build*, *platform*, *service_pack*, *service_pack_minor*, *service_pack_major*, *suite_mask*, *product_type* and *platform_version*. *service_pack* contains a string, *platform_version* a 3-tuple and all other values are integers. The components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

platform will be **`2 (VER_PLATFORM_WIN32_NT)`**.

product_type may be one of the following values:

Constant	Meaning
`1 (VER_NT_WORKSTATION)`	The system is a workstation.
`2 (VER_NT_DOMAIN_CONTROLLER)`	The system is a domain controller.
`3 (VER_NT_SERVER)`	The system is a server, but not a domain controller.

This function wraps the Win32 **`GetVersionEx()`** function; see the Microsoft documentation on **`OSVERSIONINFOEX()`** for more information about these fields.

platform_version returns the major version, minor version and build number of the current operating system, rather than the version that is being emulated for the process. It is intended for use in logging rather than for feature detection.

Note

platform_version derives the version from kernel32.dll which can be of a different version than the OS version. Please use **`platform`** module for achieving accurate OS version.

Availability: Windows.

Changed in version 3.2: Changed to a named tuple and added *service_pack_minor*, *service_pack_major*, *suite_mask*, and *product_type*.

Changed in version 3.6: Added *platform_version*

sys.get_asyncgen_hooks()

Returns an *asyncgen_hooks* object, which is similar to a **namedtuple** of the form `(firstiter, finalizer)`, where *firstiter* and *finalizer* are expected to be either `None` or functions which take an asynchronous generator iterator as an argument, and are used to schedule finalization of an asynchronous generator by an event loop.

New in version 3.6: See **PEP 525** [https://peps.python.org/pep-0525/] for more details.

Note

This function has been added on a provisional basis (see **PEP 411** [https://peps.python.org/pep-0411/] for details.)

sys.get_coroutine_origin_tracking_depth()

Get the current coroutine origin tracking depth, as set by **set_coroutine_origin_tracking_depth()**.

New in version 3.7.

Note

This function has been added on a provisional basis (see **PEP 411** [https://peps.python.org/pep-0411/] for details.) Use it only for debugging purposes.

sys.hash_info

A named tuple giving parameters of the numeric hash implementation. For more details about hashing of numeric types, see Hashing of numeric types.

attribute	explanation
width	width in bits used for hash values
modulus	prime modulus P used for numeric hash scheme
inf	hash value returned for a positive infinity
nan	(this attribute is no longer used)
imag	multiplier used for the imaginary part of a complex number
algorithm	name of the algorithm for hashing of str, bytes, and memoryview
hash_bits	internal output size of the hash algorithm
seed_bits	size of the seed key of the hash algorithm

New in version 3.2.

Changed in version 3.4: Added *algorithm*, *hash_bits* and *seed_bits*

sys.hexversion

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```
if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the
    ...
```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in **`hex()`** function. The named tuple **`sys.version_info`** may be used for a more human-friendly encoding of the same information.

More details of `hexversion` can be found at API and ABI

Versioning.

sys.implementation

An object containing information about the implementation of the currently running Python interpreter. The following attributes are required to exist in all Python implementations.

name is the implementation's identifier, e.g. `'cpython'`. The actual string is defined by the Python implementation, but it is guaranteed to be lower case.

version is a named tuple, in the same format as **`sys.version_info`**. It represents the version of the Python *implementation*. This has a distinct meaning from the specific version of the Python *language* to which the currently running interpreter conforms, which `sys.version_info` represents. For example, for PyPy 1.8 `sys.implementation.version` might be `sys.version_info(1, 8, 0, 'final', 0)`, whereas `sys.version_info` would be `sys.version_info(2, 7, 2, 'final', 0)`. For CPython they are the same value, since it is the reference implementation.

hexversion is the implementation version in hexadecimal format, like **`sys.hexversion`**.

cache_tag is the tag used by the import machinery in the filenames of cached modules. By convention, it would be a composite of the implementation's name and version, like `'cpython-33'`. However, a Python implementation may use some other value if appropriate. If `cache_tag` is set to `None`, it indicates that module caching should be disabled.

`sys.implementation` may contain additional attributes specific to the Python implementation. These non-standard attributes must start with an underscore, and are not described here. Regardless of its contents, **`sys.implementation`** will not change during a run of the interpreter, nor between implementation versions. (It may change between Python language versions, however.) See

PEP 421 [https://peps.python.org/pep-0421/] for more information.

New in version 3.3.

Note

The addition of new required attributes must go through the normal PEP process. See **PEP 421** [https://peps.python.org/pep-0421/] for more information.

sys.int_info

A named tuple that holds information about Python's internal representation of integers. The attributes are read only.

Attribute	Explanation
bits_per_digit	number of bits held in each digit. Python integers are stored internally in base `2**int_info.bits_per_digit`
sizeof_digit	size in bytes of the C type used to represent a digit
default_max_str_digits	default value for **sys.get_int_max_str_digits()** when it is not otherwise explicitly configured.
str_digits_check_threshold	minimum non-zero value for **sys.set_int_max_str_digits()**, **PYTHONINTMAXSTRDIGITS**, or **-X int_max_str_digits**.

New in version 3.1.

Changed in version 3.11: Added `default_max_str_digits` and `str_digits_check_threshold`.

sys._interactivehook_

When this attribute exists, its value is automatically called (with no arguments) when the interpreter is launched in interactive mode. This is done after the **PYTHONSTARTUP** file is read, so that you can set this hook there. The **site** module sets this.

Raises an auditing event `cpython.run_interactivehook` with the hook object as the argument when the hook is called on startup.

New in version 3.4.

sys.intern(*string*)

Enter *string* in the table of "interned" strings and return the interned string – which is *string* itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup – if the keys in a dictionary are interned, and the lookup key is interned, the key comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Interned strings are not immortal; you must keep a reference to the return value of **`intern()`** around to benefit from it.

sys.is_finalizing()

Return **`True`** if the Python interpreter is shutting down, **`False`** otherwise.

New in version 3.5.

sys.last_type
sys.last_value
sys.last_traceback

These three variables are not always defined; they are set when an exception is not handled and the interpreter prints an error message and a stack traceback. Their intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see **`pdb`** module for more information.)

The meaning of the variables is the same as that of the return values from **exc_info()** above.

sys.maxsize

An integer giving the maximum value a variable of type **Py_ssize_t** can take. It's usually `2**31 - 1` on a 32-bit platform and `2**63 - 1` on a 64-bit platform.

sys.maxunicode

An integer giving the value of the largest Unicode code point, i.e. `1114111` (`0x10FFFF` in hexadecimal).

Changed in version 3.3: Before **PEP 393** [https://peps.python.org/pep-0393/], `sys.maxunicode` used to be either `0xFFFF` or `0x10FFFF`, depending on the configuration option that specified whether Unicode characters were stored as UCS-2 or UCS-4.

sys.meta_path

A list of meta path finder objects that have their **find_spec()** methods called to see if one of the objects can find the module to be imported. By default, it holds entries that implement Python's default import semantics. The **find_spec()** method is called with at least the absolute name of the module being imported. If the module to be imported is contained in a package, then the parent package's **__path__** attribute is passed in as a second argument. The method returns a module spec, or `None` if the module cannot be found.

See also

importlib.abc.MetaPathFinder
The abstract base class defining the interface of finder objects on **meta_path**.

importlib.machinery.ModuleSpec
The concrete class which **find_spec()** should return instances of.

Changed in version 3.4: Module specs were introduced in Python 3.4, by **PEP 451** [https://peps.python.org/pep-0451/]. Earlier versions of Python looked for a method called **find_module()**. This is still called as a fallback if a **meta_path** entry doesn't have a **find_spec()** method.

sys.modules

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. However, replacing the dictionary will not necessarily work as expected and deleting essential items from the dictionary may cause Python to fail. If you want to iterate over this global dictionary always use `sys.modules.copy()` or `tuple(sys.modules)` to avoid exceptions as its size may change during iteration as a side effect of code or activity in other threads.

sys.orig_argv

The list of the original command line arguments passed to the Python executable.

See also **sys.argv**.

New in version 3.10.

sys.path

A list of strings that specifies the search path for modules. Initialized from the environment variable **PYTHONPATH**, plus an installation-dependent default.

By default, as initialized upon program startup, a potentially unsafe path is prepended to **sys.path** (*before* the entries inserted as a result of **PYTHONPATH**):

- `python -m module` command line: prepend the current working directory.
- `python script.py` command line: prepend the script's directory. If it's a symbolic link, resolve symbolic links.

- `python -c code` and `python` (REPL) command lines: prepend an empty string, which means the current working directory.

To not prepend this potentially unsafe path, use the **`-P`** command line option or the **`PYTHONSAFEPATH`** environment variable.

A program is free to modify this list for its own purposes. Only strings should be added to **`sys.path`**; all other data types are ignored during import.

See also

- Module **`site`** This describes how to use .pth files to extend **`sys.path`**.

sys.path_hooks

A list of callables that take a path argument to try to create a finder for the path. If a finder can be created, it is to be returned by the callable, else raise **`ImportError`**.

Originally specified in **PEP 302** [https://peps.python.org/pep-0302/].

sys.path_importer_cache

A dictionary acting as a cache for finder objects. The keys are paths that have been passed to **`sys.path_hooks`** and the values are the finders that are found. If a path is a valid file system path but no finder is found on **`sys.path_hooks`** then `None` is stored.

Originally specified in **PEP 302** [https://peps.python.org/pep-0302/].

Changed in version 3.3: `None` is stored instead of **`imp.NullImporter`** when no finder is found.

sys.platform

This string contains a platform identifier that can be used to append platform-specific components to **sys.path**, for instance.

For Unix systems, except on Linux and AIX, this is the lowercased OS name as returned by `uname -s` with the first part of the version as returned by `uname -r` appended, e.g. `'sunos5'` or `'freebsd8'`, *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
elif sys.platform.startswith('linux'):
    # Linux-specific code here...
elif sys.platform.startswith('aix'):
    # AIX-specific code here...
```

For other systems, the values are:

System	**sys.platform** value
AIX	`'aix'`
Emscripten	`'emscripten'`
Linux	`'linux'`
WASI	`'wasi'`
Windows	`'win32'`
Windows/Cygwin	`'cygwin'`
macOS	`'darwin'`

Changed in version 3.3: On Linux, **sys.platform** doesn't contain the major version anymore. It is always `'linux'`, instead of `'linux2'` or `'linux3'`. Since older Python versions include the version number, it is recommended to always use the `startswith` idiom presented above.

Changed in version 3.8: On AIX, **sys.platform** doesn't contain the major version anymore. It is always `'aix'`, instead of `'aix5'` or `'aix7'`. Since older Python versions include the version number, it is recommended to always use the `startswith` idiom presented above.

See also

os.name has a coarser granularity. **os.uname()** gives system-dependent version information.

The **platform** module provides detailed checks for the system's identity.

sys.platlibdir

Name of the platform-specific library directory. It is used to build the path of standard library and the paths of installed extension modules.

It is equal to `"lib"` on most platforms. On Fedora and SuSE, it is equal to `"lib64"` on 64-bit platforms which gives the following `sys.path` paths (where `X.Y` is the Python `major.minor` version):

- `/usr/lib64/pythonX.Y/`: Standard library (like `os.py` of the **os** module)
- `/usr/lib64/pythonX.Y/lib-dynload/`: C extension modules of the standard library (like the **errno** module, the exact filename is platform specific)
- `/usr/lib/pythonX.Y/site-packages/` (always use `lib`, not **sys.platlibdir**): Third-party modules
- `/usr/lib64/pythonX.Y/site-packages/`: C extension modules of third-party packages

New in version 3.9.

sys.prefix

A string giving the site-specific directory prefix where the platform independent Python files are installed; on Unix, the default is `'/usr/local'`. This can be set at build time with the `--prefix` argument to the **configure** script. See Installation paths for derived paths.

Note

If a virtual environment is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via **`base_prefix`**.

sys.ps1
sys.ps2

Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are `'>>> '` and `'... '`. If a non-string object is assigned to either variable, its **`str()`** is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.

sys.setdlopenflags(*n*)

Set the flags used by the interpreter for **`dlopen()`** calls, such as when the interpreter loads extension modules. Among other things, this will enable a lazy resolving of symbols when importing a module, if called as `sys.setdlopenflags(0)`. To share symbols across extension modules, call as `sys.setdlopenflags(os.RTLD_GLOBAL)`. Symbolic names for the flag values can be found in the **`os`** module (`RTLD_xxx` constants, e.g. **`os.RTLD_LAZY`**).

Availability: Unix.

sys.set_int_max_str_digits(*maxdigits*)

Set the integer string conversion length limitation used by this interpreter. See also **`get_int_max_str_digits()`**.

New in version 3.11.

sys.setprofile(*profilefunc*)

Set the system's profile function, which allows you to implement a Python source code profiler in Python. See

chapter The Python Profilers for more information on the Python profiler. The system's profile function is called similarly to the system's trace function (see **`settrace()`**), but it is called with different events, for example it isn't called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return `None`. Error in the profile function will cause itself unset.

Profile functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: `'call'`, `'return'`, `'c_call'`, `'c_return'`, or `'c_exception'`. *arg* depends on the event type.

Raises an auditing event `sys.setprofile` with no arguments.

The events have the following meaning:

`'call'`
: A function is called (or some other code block entered). The profile function is called; *arg* is `None`.

`'return'`
: A function (or other code block) is about to return. The profile function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised.

`'c_call'`
: A C function is about to be called. This may be an extension function or a built-in. *arg* is the C function object.

`'c_return'`
: A C function has returned. *arg* is the C function object.

`'c_exception'`
: A C function has raised an exception. *arg* is the C function object.

sys.setrecursionlimit(*limit*)
: Set the maximum depth of the Python interpreter stack to *limit*. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

  The highest possible limit is platform-dependent. A user may need to set the limit higher when they have a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

  If the new limit is too low at the current recursion depth, a **`RecursionError`** exception is raised.

  Changed in version 3.5.1: A **`RecursionError`** exception is now raised if the new limit is too low at the current recursion depth.

sys.setswitchinterval(*interval*)
: Set the interpreter's thread switch interval (in seconds). This floating-point value determines the ideal duration of the "timeslices" allocated to concurrently running Python threads. Please note that the actual value can be higher, especially if long-running internal functions or methods are used. Also, which thread becomes scheduled at the end of the interval is the operating system's decision. The interpreter doesn't have its own scheduler.

  New in version 3.2.

sys.settrace(*tracefunc*)
: Set the system's trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must register a trace function using **`settrace()`**

for each thread being debugged or use **`threading.settrace()`**.

Trace functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: `'call'`, `'line'`, `'return'`, `'exception'` or `'opcode'`. *arg* depends on the event type.

The trace function is invoked (with *event* set to `'call'`) whenever a new local scope is entered; it should return a reference to a local trace function to be used for the new scope, or `None` if the scope shouldn't be traced.

The local trace function should return a reference to itself (or to another function for further tracing in that scope), or `None` to turn off tracing in that scope.

If there is any error occurred in the trace function, it will be unset, just like `settrace(None)` is called.

The events have the following meaning:

`'call'`
: A function is called (or some other code block entered). The global trace function is called; *arg* is `None`; the return value specifies the local trace function.

`'line'`
: The interpreter is about to execute a new line of code or re-execute the condition of a loop. The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. See `Objects/lnotab_notes.txt` for a detailed explanation of how this works. Per-line events may be disabled for a frame by setting **`f_trace_lines`** to **`False`** on that frame.

`'return'`
: A function (or other code block) is about to return. The local trace function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised. The trace function's return

value is ignored.

`'exception'`
: An exception has occurred. The local trace function is called; *arg* is a tuple `(exception, value, traceback)`; the return value specifies the new local trace function.

`'opcode'`
: The interpreter is about to execute a new opcode (see **`dis`** for opcode details). The local trace function is called; *arg* is `None`; the return value specifies the new local trace function. Per-opcode events are not emitted by default: they must be explicitly requested by setting **`f_trace_opcodes`** to **`True`** on the frame.

Note that as an exception is propagated down the chain of callers, an `'exception'` event is generated at each level.

For more fine-grained usage, it's possible to set a trace function by assigning `frame.f_trace = tracefunc` explicitly, rather than relying on it being set indirectly via the return value from an already installed trace function. This is also required for activating the trace function on the current frame, which **`settrace()`** doesn't do. Note that in order for this to work, a global tracing function must have been installed with **`settrace()`** in order to enable the runtime tracing machinery, but it doesn't need to be the same tracing function (e.g. it could be a low overhead tracing function that simply returns `None` to disable itself immediately on each frame).

For more information on code and frame objects, refer to The standard type hierarchy.

Raises an auditing event `sys.settrace` with no arguments.

CPython implementation detail: The **`settrace()`** function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language

definition, and thus may not be available in all Python implementations.

Changed in version 3.7: `'opcode'` event type added; **`f_trace_lines`** and **`f_trace_opcodes`** attributes added to frames

sys.set_asyncgen_hooks(*firstiter*, *finalizer*)

Accepts two optional keyword arguments which are callables that accept an asynchronous generator iterator as an argument. The *firstiter* callable will be called when an asynchronous generator is iterated for the first time. The *finalizer* will be called when an asynchronous generator is about to be garbage collected.

Raises an auditing event `sys.set_asyncgen_hooks_firstiter` with no arguments.

Raises an auditing event `sys.set_asyncgen_hooks_finalizer` with no arguments.

Two auditing events are raised because the underlying API consists of two calls, each of which must raise its own event.

New in version 3.6: See **PEP 525** [https://peps.python.org/pep-0525/] for more details, and for a reference example of a *finalizer* method see the implementation of `asyncio.Loop.shutdown_asyncgens` in Lib/asyncio/base_events.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_events.py]

Note

This function has been added on a provisional basis (see **PEP 411** [https://peps.python.org/pep-0411/] for details.)

sys.set_coroutine_origin_tracking_depth(*depth*)

Allows enabling or disabling coroutine origin tracking. When enabled, the `cr_origin` attribute on coroutine objects will contain a tuple of (filename, line number, function name) tuples describing the traceback where the coroutine object was created, with the most recent call first. When disabled, `cr_origin` will be None.

To enable, pass a *depth* value greater than zero; this sets the number of frames whose information will be captured. To disable, pass set *depth* to zero.

This setting is thread-specific.

New in version 3.7.

Note

This function has been added on a provisional basis (see **PEP 411** [https://peps.python.org/pep-0411/] for details.) Use it only for debugging purposes.

sys._enablelegacywindowsfsencoding()

Changes the filesystem encoding and error handler to 'mbcs' and 'replace' respectively, for consistency with versions of Python prior to 3.6.

This is equivalent to defining the **PYTHONLEGACYWINDOWSFSENCODING** environment variable before launching Python.

See also **sys.getfilesystemencoding()** and **sys.getfilesystemencodeerrors()**.

Availability: Windows.

New in version 3.6: See **PEP 529** [https://peps.python.org/pep-0529/] for more details.

sys.stdin

sys.stdout
sys.stderr

File objects used by the interpreter for standard input, output and errors:

- `stdin` is used for all interactive input (including calls to **`input()`**);
- `stdout` is used for the output of **`print()`** and expression statements and for the prompts of **`input()`**;
- The interpreter's own prompts and its error messages go to `stderr`.

These streams are regular text files like those returned by the **`open()`** function. Their parameters are chosen as follows:

- The encoding and error handling are is initialized from **`PyConfig.stdio_encoding`** and **`PyConfig.stdio_errors`**.

  On Windows, UTF-8 is used for the console device. Non-character devices such as disk files and pipes use the system locale encoding (i.e. the ANSI codepage). Non-console character devices such as NUL (i.e. where `isatty()` returns `True`) use the value of the console input and output codepages at startup, respectively for stdin and stdout/stderr. This defaults to the system locale encoding if the process is not initially attached to a console.

  The special behaviour of the console can be overridden by setting the environment variable PYTHONLEGACYWINDOWSSTDIO before starting Python. In that case, the console codepages are used as for any other character device.

  Under all platforms, you can override the character encoding by setting the **`PYTHONIOENCODING`** environment variable before starting Python or by using the new **`-X`** `utf8` command line option and **`PYTHONUTF8`** environment variable. However, for the

Windows console, this only applies when **PYTHONLEGACYWINDOWSSTDIO** is also set.

- When interactive, the `stdout` stream is line-buffered. Otherwise, it is block-buffered like regular text files. The `stderr` stream is line-buffered in both cases. You can make both streams unbuffered by passing the **-u** command-line option or setting the **PYTHONUNBUFFERED** environment variable.

Changed in version 3.9: Non-interactive `stderr` is now line-buffered instead of fully buffered.

Note

To write or read binary data from/to the standard streams, use the underlying binary **buffer** object. For example, to write bytes to **stdout**, use `sys.stdout.buffer.write(b'abc')`.

However, if you are writing a library (and do not control in which context its code will be executed), be aware that the standard streams may be replaced with file-like objects like **io.StringIO** which do not support the **buffer** attribute.

sys.__stdin__
sys.__stdout__
sys.__stderr__

These objects contain the original values of `stdin`, `stderr` and `stdout` at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the previous stream before replacing it, and

restore the saved object.

Note

Under some conditions `stdin`, `stdout` and `stderr` as well as the original values `__stdin__`, `__stdout__` and `__stderr__` can be `None`. It is usually the case for Windows GUI apps that aren't connected to a console and Python apps started with **pythonw**.

sys.stdlib_module_names

A frozenset of strings containing the names of standard library modules.

It is the same on all platforms. Modules which are not available on some platforms and modules disabled at Python build are also listed. All module kinds are listed: pure Python, built-in, frozen and extension modules. Test modules are excluded.

For packages, only the main package is listed: sub-packages and sub-modules are not listed. For example, the `email` package is listed, but the `email.mime` sub-package and the `email.message` sub-module are not listed.

See also the **`sys.builtin_module_names`** list.

New in version 3.10.

sys.thread_info

A named tuple holding information about the thread implementation.

Attribute	Explanation
Name	Name of the thread implementation: • `'nt'`: Windows threads • `'pthread'`: POSIX threads • `'pthread-stubs'`: stub POSIX threads (on WebAssembly platforms

without threading support)
- `'solaris'`: Solaris threads

Name of the lock implementation:
- `'semaphore'`: a lock uses a semaphore
- `'mutex+cond'`: a lock uses a mutex and a condition variable
- `None` if this information is unknown

Name and version of the thread library. It is a string, or `None` if this information is unknown.

New in version 3.3.

sys.tracebacklimit

When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is `1000`. When set to `0` or less, all traceback information is suppressed and only the exception type and value are printed.

sys.unraisablehook(*unraisable*, */*)

Handle an unraisable exception.

Called when an exception has occurred but there is no way for Python to handle it. For example, when a destructor raises an exception or during garbage collection (**`gc.collect()`**).

The *unraisable* argument has the following attributes:

- *exc_type*: Exception type.
- *exc_value*: Exception value, can be `None`.
- *exc_traceback*: Exception traceback, can be `None`.
- *err_msg*: Error message, can be `None`.
- *object*: Object causing the exception, can be `None`.

The default hook formats *err_msg* and *object* as: `f'{err_msg}: {object!r}'`; use "Exception ignored in" error message if *err_msg* is `None`.

`sys.unraisablehook()` can be overridden to control how

unraisable exceptions are handled.

Storing *exc_value* using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing *object* using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing *object* after the custom hook completes to avoid resurrecting objects.

See also **`excepthook()`** which handles uncaught exceptions.

Raise an auditing event `sys.unraisablehook` with arguments `hook`, `unraisable` when an exception that cannot be handled occurs. The `unraisable` object is the same as what will be passed to the hook. If no hook has been set, `hook` may be `None`.

New in version 3.8.

sys.version

A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use **`version_info`** and the functions provided by the **`platform`** module.

sys.api_version

The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

sys.version_info

A tuple containing the five components of the version number: *major*, *minor*, *micro*, *releaselevel*, and *serial*. All values except *releaselevel* are integers; the release level is `'alpha'`,

`'beta'`, `'candidate'`, or `'final'`. The `version_info` value corresponding to the Python version 2.0 is `(2, 0, 0, 'final', 0)`. The components can also be accessed by name, so `sys.version_info[0]` is equivalent to `sys.version_info.major` and so on.

Changed in version 3.1: Added named component attributes.

sys.warnoptions

This is an implementation detail of the warnings framework; do not modify this value. Refer to the **warnings** module for more information on the warnings framework.

sys.winver

The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the first three characters of **version**. It is provided in the **sys** module for informational purposes; modifying this value has no effect on the registry keys used by Python.

Availability: Windows.

sys._xoptions

A dictionary of the various implementation-specific flags passed through the **-X** command-line option. Option names are either mapped to their values, if given explicitly, or to **True**. Example:

```
$ ./python -Xa=b -Xc
Python 3.2a3+ (py3k, Oct 16 2010, 20:14:50)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license" fo
>>> import sys
>>> sys._xoptions
{'a': 'b', 'c': True}
```

CPython implementation detail: This is a CPython-specific way of accessing options passed through **-X**. Other

implementations may export them through other means, or not at all.

New in version 3.2.

`sysconfig` — Provide access to Python's configuration information

New in version 3.2.

Source code: Lib/sysconfig.py [https://github.com/python/cpython/tree/3.11/Lib/sysconfig.py]

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.

Configuration variables

A Python distribution contains a `Makefile` and a `pyconfig.h` header file that are necessary to build both the Python binary itself and third-party C extensions compiled using `distutils`.

`sysconfig` puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it's a much smaller set.

sysconfig.get_config_vars(**args*)

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return `None`.

sysconfig.get_config_var(*name*)

Return the value of a single variable *name*. Equivalent to `get_config_vars().get(name)`.

If *name* is not found, return `None`.

Example of usage:

```
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
'/usr/local/lib'
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```

Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in **`sysconfig`** under unique identifiers based on the value returned by **`os.name`**.

Every new component that is installed using **`distutils`** or a Distutils-based system will follow the same scheme to copy its file in the right places.

Python currently supports nine schemes:

- *posix_prefix*: scheme for POSIX platforms like Linux or macOS. This is the default scheme used when Python or a component is installed.
- *posix_home*: scheme for POSIX platforms used when a *home* option is used upon installation. This scheme is used when a component is installed through Distutils with a specific home prefix.
- *posix_user*: scheme for POSIX platforms used when a

component is installed through Distutils and the *user* option is used. This scheme defines paths located under the user home directory.

- *posix_venv*: scheme for **Python virtual environments** on POSIX platforms; by default it is the same as *posix_prefix* .
- *nt*: scheme for NT platforms like Windows.
- *nt_user*: scheme for NT platforms, when the *user* option is used.
- *nt_venv*: scheme for **Python virtual environments** on NT platforms; by default it is the same as *nt* .
- *venv*: a scheme with values from ether *posix_venv* or *nt_venv* depending on the platform Python runs on
- *osx_framework_user*: scheme for macOS, when the *user* option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- *stdlib*: directory containing the standard Python library files that are not platform-specific.
- *platstdlib*: directory containing the standard Python library files that are platform-specific.
- *platlib*: directory for site-specific, platform-specific files.
- *purelib*: directory for site-specific, non-platform-specific files.
- *include*: directory for non-platform-specific header files for the Python C-API.
- *platinclude*: directory for platform-specific header files for the Python C-API.
- *scripts*: directory for script files.
- *data*: directory for data files.

sysconfig provides some functions to determine these paths.

sysconfig.get_scheme_names()

Return a tuple containing all schemes currently supported in **sysconfig**.

sysconfig.get_default_scheme()

Return the default scheme name for the current platform.

New in version 3.10: This function was previously named `_get_default_scheme()` and considered an implementation detail.

Changed in version 3.11: When Python runs from a virtual environment, the *venv* scheme is returned.

sysconfig.get_preferred_scheme(*key*)

Return a preferred scheme name for an installation layout specified by *key*.

key must be either `"prefix"`, `"home"`, or `"user"`.

The return value is a scheme name listed in **`get_scheme_names()`**. It can be passed to **`sysconfig`** functions that take a *scheme* argument, such as **`get_paths()`**.

New in version 3.10.

Changed in version 3.11: When Python runs from a virtual environment and `key="prefix"`, the *venv* scheme is returned.

sysconfig._get_preferred_schemes()

Return a dict containing preferred scheme names on the current platform. Python implementers and redistributors may add their preferred schemes to the `_INSTALL_SCHEMES` module-level global value, and modify this function to return those scheme names, to e.g. provide different schemes for system and language package managers to use, so packages installed by either do not mix with those by the other.

End users should not use this function, but **`get_default_scheme()`** and **`get_preferred_scheme()`** instead.

New in version 3.10.

sysconfig.get_path_names()

Return a tuple containing all path names currently supported in **sysconfig**.

sysconfig.get_path(*name*[, *scheme*[, *vars*[, *expand*]]])

Return an installation path corresponding to the path *name*, from the install scheme named *scheme*.

name has to be a value from the list returned by **get_path_names()**.

sysconfig stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the *stdlib* path for the *nt* scheme is: `{base}/Lib`.

get_path() will use the variables returned by **get_config_vars()** to expand the path. All variables have default values for each platform so one may call this function and get the default value.

If *scheme* is provided, it must be a value from the list returned by **get_scheme_names()**. Otherwise, the default scheme for the current platform is used.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary return by **get_config_vars()**.

If *expand* is set to `False`, the path will not be expanded using the variables.

If *name* is not found, raise a **KeyError**.

sysconfig.get_paths([*scheme*[, *vars*[, *expand*]]])

Return a dictionary containing all installation paths corresponding to an installation scheme. See **get_path()** for more information.

If *scheme* is not provided, will use the default scheme for the current platform.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If *expand* is set to false, the paths will not be expanded.

If *scheme* is not an existing scheme, **`get_paths()`** will raise a **`KeyError`**.

Other functions

sysconfig.get_python_version()

Return the `MAJOR.MINOR` Python version number as a string. Similar to `'%d.%d' % sys.version_info[:2]`.

sysconfig.get_platform()

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by 'os.uname()'), although the exact information included depends on the OS; e.g., on Linux, the kernel version isn't particularly important.

Examples of returned values:

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u

Windows will return one of:

- win-amd64 (64bit Windows on AMD64, aka x86_64, Intel64, and EM64T)
- win32 (all others - specifically, sys.platform is returned)

macOS can return:

- macosx-10.6-ppc
- macosx-10.4-ppc64

- macosx-10.3-i386
- macosx-10.4-fat

For other non-POSIX platforms, currently just returns **sys.platform**.

sysconfig.is_python_build()

Return `True` if the running Python interpreter was built from source and is being run from its built location, and not from a location resulting from e.g. running `make install` or installing via a binary installer.

sysconfig.parse_config_h(*fp*[, *vars*])

Parse a `config.h`-style file.

fp is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

sysconfig.get_config_h_filename()

Return the path of `pyconfig.h`.

sysconfig.get_makefile_filename()

Return the path of `Makefile`.

Using **sysconfig** as a script

You can use **sysconfig** as a script with Python's *-m* option:

```
$ python -m sysconfig
Platform: "macosx-10.4-i386"
Python version: "3.2"
Current installation scheme: "posix_prefix"
```

```
Paths:
        data = "/usr/local"
        include = "/Users/tarek/Dev/svn.python.org/py3k/
        platinclude = "."
        platlib = "/usr/local/lib/python3.2/site-package
        platstdlib = "/usr/local/lib/python3.2"
        purelib = "/usr/local/lib/python3.2/site-package
        scripts = "/usr/local/bin"
        stdlib = "/usr/local/lib/python3.2"

Variables:
        AC_APPLE_UNIVERSAL_BUILD = "0"
        AIX_GENUINE_CPLUSPLUS = "0"
        AR = "ar"
        ARFLAGS = "rc"
        ...
```

This call will print in the standard output the information returned by **`get_platform()`**, **`get_python_version()`**, **`get_path()`** and **`get_config_vars()`**.

`builtins` — Built-in objects

This module provides direct access to all 'built-in' identifiers of Python; for example, `builtins.open` is the full name for the built-in function **`open()`**. See Built-in Functions and Built-in Constants for documentation.

This module is not normally accessed explicitly by most applications, but can be useful in modules that provide objects with the same name as a built-in value, but in which the built-in of that name is also needed. For example, in a module that wants to implement an **`open()`** function that wraps the built-in **`open()`**, this module can be used directly:

```
import builtins

def open(path):
    f = builtins.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''Wrapper around a file that converts output to upp

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

    # ...
```

As an implementation detail, most modules have the name `__builtins__` made available as part of their globals. The value of `__builtins__` is normally either this module or the value of this module's **`__dict__`** attribute. Since this is an implementation

detail, it may not be used by alternate implementations of Python.

`__main__` — Top-level code environment

In Python, the special name `__main__` is used for two important constructs:

1. the name of the top-level environment of the program, which can be checked using the `__name__ == '__main__'` expression; and
2. the `__main__.py` file in Python packages.

Both of these mechanisms are related to Python modules; how users interact with them and how they interact with each other. They are explained in detail below. If you're new to Python modules, see the tutorial section Modules for an introduction.

`__name__ == '__main__'`

When a Python module or package is imported, `__name__` is set to the module's name. Usually, this is the name of the Python file itself without the `.py` extension:

```
>>> import configparser
>>> configparser.__name__
'configparser'
```

If the file is part of a package, `__name__` will also include the parent package's path:

```
>>> from concurrent.futures import process
>>> process.__name__
'concurrent.futures.process'
```

However, if the module is executed in the top-level code

environment, its `__name__` is set to the string `'__main__'`.

What is the “top-level code environment”?

`__main__` is the name of the environment where top-level code is run. “Top-level code” is the first user-specified Python module that starts running. It’s “top-level” because it imports all other modules that the program needs. Sometimes “top-level code” is called an *entry point* to the application.

The top-level code environment can be:

- the scope of an interactive prompt:

  ```
  >>> __name__
  '__main__'
  ```

- the Python module passed to the Python interpreter as a file argument:

  ```
  $ python3 helloworld.py
  Hello, world!
  ```

- the Python module or package passed to the Python interpreter with the `-m` argument:

  ```
  $ python3 -m tarfile
  usage: tarfile.py [-h] [-v] (...)
  ```

- Python code read by the Python interpreter from standard input:

  ```
  $ echo "import this" | python3
  The Zen of Python, by Tim Peters

  Beautiful is better than ugly.
  Explicit is better than implicit.
  ...
  ```

- Python code passed to the Python interpreter with the `-c` argument:

```
$ python3 -c "import this"
The Zen of Python, by Tim Peters

Beautiful is better than ugly.
Explicit is better than implicit.
...
```

In each of these situations, the top-level module's `__name__` is set to `'__main__'`.

As a result, a module can discover whether or not it is running in the top-level environment by checking its own `__name__`, which allows a common idiom for conditionally executing code when the module is not initialized from an import statement:

```
if __name__ == '__main__':
    # Execute when the module is not initialized from ar
    ...
```

See also

For a more detailed look at how `__name__` is set in all situations, see the tutorial section Modules.

Idiomatic Usage

Some modules contain code that is intended for script use only, like parsing command-line arguments or fetching data from standard input. If a module like this was imported from a different module, for example to unit test it, the script code would unintentionally execute as well.

This is where using the `if __name__ == '__main__'` code block comes in handy. Code within this block won't run unless the module is executed in the top-level environment.

Putting as few statements as possible in the block below `if __name___ == '__main__'` can improve code clarity and correctness. Most often, a function named `main` encapsulates the program's primary behavior:

```
# echo.py

import shlex
import sys

def echo(phrase: str) -> None:
    """A dummy wrapper around print."""
    # for demonstration purposes, you can imagine that th
    # valuable and reusable logic inside this function
    print(phrase)

def main() -> int:
    """Echo the input arguments to standard output"""
    phrase = shlex.join(sys.argv)
    echo(phrase)
    return 0

if __name__ == '__main__':
    sys.exit(main())  # next section explains the use of
```

Note that if the module didn't encapsulate code inside the `main` function but instead put it directly within the `if __name__ == '__main__'` block, the `phrase` variable would be global to the entire module. This is error-prone as other functions within the module could be unintentionally using the global variable instead of a local name. A `main` function solves this problem.

Using a `main` function has the added benefit of the `echo` function itself being isolated and importable elsewhere. When `echo.py` is imported, the `echo` and `main` functions will be defined, but neither of them will be called, because `__name__ != '__main__'`.

Packaging Considerations

`main` functions are often used to create command-line tools by specifying them as entry points for console scripts. When this is done, pip [https://pip.pypa.io/] inserts the function call into a template script, where the return value of `main` is passed into

`sys.exit()`. For example:

```
sys.exit(main())
```

Since the call to `main` is wrapped in **`sys.exit()`**, the expectation is that your function will return some value acceptable as an input to **`sys.exit()`**; typically, an integer or `None` (which is implicitly returned if your function does not have a return statement).

By proactively following this convention ourselves, our module will have the same behavior when run directly (i.e. `python3 echo.py`) as it will have if we later package it as a console script entry-point in a pip-installable package.

In particular, be careful about returning strings from your `main` function. **`sys.exit()`** will interpret a string argument as a failure message, so your program will have an exit code of `1`, indicating failure, and the string will be written to **`sys.stderr`**. The `echo.py` example from earlier exemplifies using the `sys.exit(main())` convention.

Python Packaging User Guide [https://packaging.python.org/] contains a collection of tutorials and references on how to distribute and install Python packages with modern tools.

`__main__.py` in Python Packages

If you are not familiar with Python packages, see section Packages of the tutorial. Most commonly, the `__main__.py` file is used to provide a command-line interface for a package. Consider the following hypothetical package, “bandclass”:

```
bandclass
     __init__.py
     __main__.py
     student.py
```

`__main__.py` will be executed when the package itself is invoked directly from the command line using the **`-m`** flag. For example:

```
$ python3 -m bandclass
```

This command will cause `__main__.py` to run. How you utilize this mechanism will depend on the nature of the package you are writing, but in this hypothetical case, it might make sense to allow the teacher to search for students:

```
# bandclass/__main__.py

import sys
from .student import search_students

student_name = sys.argv[2] if len(sys.argv) >= 2 else ''
print(f'Found student: {search_students(student_name)}')
```

Note that `from .student import search_students` is an example of a relative import. This import style can be used when referencing modules within a package. For more details, see Intra-package References in the Modules section of the tutorial.

Idiomatic Usage

The contents of `__main__.py` typically isn't fenced with `if __name__ == '__main__'` blocks. Instead, those files are kept short, functions to execute from other modules. Those other modules can then be easily unit-tested and are properly reusable.

If used, an `if __name__ == '__main__'` block will still work as expected for a `__main__.py` file within a package, because its `__name__` attribute will include the package's path if imported:

```
>>> import asyncio.__main__
>>> asyncio.__main__.__name__
'asyncio.__main__'
```

This won't work for `__main__.py` files in the root directory of a .zip file though. Hence, for consistency, minimal `__main__.py` like the **`venv`** one mentioned below are preferred.

See also

See **venv** for an example of a package with a minimal `__main__.py` in the standard library. It doesn't contain a `if __name__ == '__main__'` block. You can invoke it with `python3 -m venv [directory]`.

See **runpy** for more details on the **-m** flag to the interpreter executable.

See **zipapp** for how to run applications packaged as *.zip* files. In this case Python looks for a `__main__.py` file in the root directory of the archive.

import __main__

Regardless of which module a Python program was started with, other modules running within that same program can import the top-level environment's scope (namespace) by importing the `__main__` module. This doesn't import a `__main__.py` file but rather whichever module that received the special name `'__main__'`.

Here is an example module that consumes the `__main__` namespace:

```
# namely.py

import __main__

def did_user_define_their_name():
    return 'my_name' in dir(__main__)

def print_user_name():
    if not did_user_define_their_name():
        raise ValueError('Define the variable `my_name`!

    if '__file__' in dir(__main__):
        print(__main__.my_name, "found in file", __main_
```

```
    else:
        print(__main__.my_name)
```

Example usage of this module could be as follows:

```
# start.py

import sys

from namely import print_user_name

# my_name = "Dinsdale"

def main():
    try:
        print_user_name()
    except ValueError as ve:
        return str(ve)

if __name__ == "__main__":
    sys.exit(main())
```

Now, if we started our program, the result would look like this:

```
$ python3 start.py
Define the variable `my_name`!
```

The exit code of the program would be 1, indicating an error. Uncommenting the line with `my_name = "Dinsdale"` fixes the program and now it exits with status code 0, indicating success:

```
$ python3 start.py
Dinsdale found in file /path/to/start.py
```

Note that importing `__main__` doesn't cause any issues with unintentionally running top-level code meant for script use which is put in the `if __name__ == "__main__"` block of the `start` module. Why does this work?

Python inserts an empty `__main__` module in **`sys.modules`** at

interpreter startup, and populates it by running top-level code. In our example this is the `start` module which runs line by line and imports `namely`. In turn, `namely` imports `__main__` (which is really `start`). That's an import cycle! Fortunately, since the partially populated `__main__` module is present in **`sys.modules`**, Python passes that to `namely`. See Special considerations for _main_ in the import system's reference for details on how this works.

The Python REPL is another example of a "top-level environment", so anything defined in the REPL becomes part of the `__main__` scope:

```
>>> import namely
>>> namely.did_user_define_their_name()
False
>>> namely.print_user_name()
Traceback (most recent call last):
...
ValueError: Define the variable `my_name`!
>>> my_name = 'Jabberwocky'
>>> namely.did_user_define_their_name()
True
>>> namely.print_user_name()
Jabberwocky
```

Note that in this case the `__main__` scope doesn't contain a `__file__` attribute as it's interactive.

The `__main__` scope is used in the implementation of **`pdb`** and **`rlcompleter`**.

`warnings` — Warning control

Source code: Lib/warnings.py [https://github.com/python/cpython/tree/3.11/Lib/warnings.py]

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn't warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see Exception Handling for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the warning category, the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the warning filter, which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default

implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

See also

`logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.

Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings.

While these are technically built-in exceptions, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the `Warning` class.

The following warnings category classes are currently defined:

Class	Description
`Warning`	This is the base class of all warning category classes. It is a subclass of `Exception`.
`UserWarning`	The default category for `warn()`.
`DeprecationWarning`	Base category for warnings about deprecated features when those warnings are intended for other Python developers (ignored by default, unless triggered by code in `__main__`).
`SyntaxWarning`	Base category for warnings about dubious syntactic features.
`RuntimeWarning`	Base category for warnings about dubious runtime features.
`FutureWarning`	Base category for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.
`PendingDeprecationWarning`	Base category for warnings about features that will be deprecated in the future (ignored by default).

ImportWarning Base category for warnings triggered during the process of importing a module (ignored by default).

UnicodeWarning Base category for warnings related to Unicode.

BytesWarning Base category for warnings related to `bytes` and `bytearray`.

ResourceWarning Base category for warnings related to resource usage (ignored by default).

Changed in version 3.7: Previously `DeprecationWarning` and `FutureWarning` were distinguished based on whether a feature was being removed entirely or changing its behaviour. They are now distinguished based on their intended audience and the way they're handled by the default warnings filters.

The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the filter determines the disposition of the match. Each entry is a tuple of the form (*action*, *message*, *category*, *module*, *lineno*), where:

- *action* is one of the following strings:

Value	Disposition
`"default"`	print the first occurrence of matching warnings for each location (module + line number) where the warning is issued
`"error"`	turn matching warnings into exceptions
`"ignore"`	never print matching warnings
`"always"`	always print matching warnings
`"module"`	print the first occurrence of matching warnings for each module where the warning is issued (regardless of line number)
`"once"`	print only the first occurrence of matching warnings, regardless of location

- *message* is a string containing a regular expression that the

start of the warning message must match, case-insensitively. In **`-W`** and **`PYTHONWARNINGS`**, *message* is a literal string that the start of the warning message must contain (case-insensitively), ignoring any whitespace at the start or end of *message*.

- *category* is a class (a subclass of **`Warning`**) of which the warning category must be a subclass in order to match.
- *module* is a string containing a regular expression that the start of the fully qualified module name must match, case-sensitively. In **`-W`** and **`PYTHONWARNINGS`**, *module* is a literal string that the fully qualified module name must be equal to (case-sensitively), ignoring any whitespace at the start or end of *module*.
- *lineno* is an integer that the line number where the warning occurred must match, or `0` to match all line numbers.

Since the **`Warning`** class is derived from the built-in **`Exception`** class, to turn a warning into an error we simply raise `category(message)`.

If a warning is reported and doesn't match any registered filter then the "default" action is applied (hence its name).

Describing Warning Filters

The warnings filter is initialized by **`-W`** options passed to the Python interpreter command line and the **`PYTHONWARNINGS`** environment variable. The interpreter saves the arguments for all supplied entries without interpretation in **`sys.warnoptions`**; the **`warnings`** module parses these when it is first imported (invalid options are ignored, after printing a message to **`sys.stderr`**).

Individual warnings filters are specified as a sequence of fields separated by colons:

```
action:message:category:module:line
```

The meaning of each of these fields is as described in The Warnings

Filter. When listing multiple filters on a single line (as for **PYTHONWARNINGS**), the individual filters are separated by commas and the filters listed later take precedence over those listed before them (as they're applied left-to-right, and the most recently applied filters take precedence over earlier ones).

Commonly used warning filters apply to either all warnings, warnings in a particular category, or warnings raised by particular modules or packages. Some examples:

```
default                         # Show all warnings (even t
ignore                          # Ignore all warnings
error                           # Convert all warnings to e
error::ResourceWarning          # Treat ResourceWarning mes
default::DeprecationWarning     # Show DeprecationWarning m
ignore,default:::mymodule       # Only report warnings trig
error:::mymodule                # Convert warnings to error
```

Default Warning Filter

By default, Python installs several warning filters, which can be overridden by the **-W** command-line option, the **PYTHONWARNINGS** environment variable and calls to **filterwarnings()**.

In regular release builds, the default warning filter has the following entries (in order of precedence):

```
default::DeprecationWarning:__main__
ignore::DeprecationWarning
ignore::PendingDeprecationWarning
ignore::ImportWarning
ignore::ResourceWarning
```

In a debug build, the list of default warning filters is empty.

Changed in version 3.2: **DeprecationWarning** is now ignored by default in addition to **PendingDeprecationWarning**.

Changed in version 3.7: **DeprecationWarning** is once again shown by default when triggered directly by code in `__main__`.

Changed in version 3.7: **BytesWarning** no longer appears in the default filter list and is instead configured via **sys.warnoptions** when **-b** is specified twice.

Overriding the default filter

Developers of applications written in Python may wish to hide *all* Python level warnings from their users by default, and only display them when running tests or otherwise working on the application. The **sys.warnoptions** attribute used to pass filter configurations to the interpreter can be used as a marker to indicate whether or not warnings should be disabled:

```
import sys

if not sys.warnoptions:
    import warnings
    warnings.simplefilter("ignore")
```

Developers of test runners for Python code are advised to instead ensure that *all* warnings are displayed by default for the code under test, using code like:

```
import sys

if not sys.warnoptions:
    import os, warnings
    warnings.simplefilter("default") # Change the filter
    os.environ["PYTHONWARNINGS"] = "default" # Also affe
```

Finally, developers of interactive shells that run user code in a namespace other than `__main__` are advised to ensure that **DeprecationWarning** messages are made visible by default, using code like the following (where `user_ns` is the module used to execute code entered interactively):

```
import warnings
warnings.filterwarnings("default", category=DeprecationW
                                   module=user_ns.get("_
```

Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning (even when warnings have been explicitly configured via the command line), then it is possible to suppress the warning using the **`catch_warnings`** context manager:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the **`catch_warnings`** context manager at the same time, the behavior is undefined.

Testing Warnings

To test warnings raised by code, use the **`catch_warnings`** context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
```

```
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert issubclass(w[-1].category, DeprecationWarning
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The **`showwarning()`** function in the module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the **`catch_warnings`** context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).

Updating Code For New Versions of Dependencies

Warning categories that are primarily of interest to Python developers (rather than end users of applications written in Python) are ignored by default.

Notably, this “ignored by default” list includes

DeprecationWarning (for every module except `__main__`), which means developers should make sure to test their code with typically ignored warnings made visible in order to receive timely notifications of future breaking API changes (whether in the standard library or third party packages).

In the ideal case, the code will have a suitable test suite, and the test runner will take care of implicitly enabling all warnings when running tests (the test runner provided by the **unittest** module does this).

In less ideal cases, applications can be checked for use of deprecated interfaces by passing **-Wd** to the Python interpreter (this is shorthand for **-W default**) or setting `PYTHONWARNINGS=default` in the environment. This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you can change what argument is passed to **-W** (e.g. **-W error**). See the **-W** flag for more details on what is possible.

Available Functions

warnings.warn(*message*, *category*=*None*, *stacklevel*=*1*, *source*=*None*)

Issue a warning, or maybe ignore it or raise an exception. The *category* argument, if given, must be a warning category class; it defaults to **UserWarning**. Alternatively, *message* can be a **Warning** instance, in which case *category* will be ignored and `message.__class__` will be used. In this case, the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the warnings filter. The *stacklevel* argument can be used by wrapper functions written in Python, like this:

```
def deprecation(message):
    warnings.warn(message, DeprecationWarning, stac
```

This makes the warning refer to **deprecation()**'s caller, rather than to the source of **deprecation()** itself (since the

latter would defeat the purpose of the warning message).

source, if supplied, is the destroyed object which emitted a **ResourceWarning**.

Changed in version 3.6: Added *source* parameter.

warnings.warn_explicit(*message*, *category*, *filename*, *lineno*, *module*=*None*, *registry*=*None*, *module_globals*=*None*, *source*=*None*)

This is a low-level interface to the functionality of **warn()**, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. *message* must be a string and *category* a subclass of **Warning** or *message* may be a **Warning** instance, in which case *category* will be ignored.

module_globals, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

source, if supplied, is the destroyed object which emitted a **ResourceWarning**.

Changed in version 3.6: Add the *source* parameter.

warnings.showwarning(*message*, *category*, *filename*, *lineno*, *file*=*None*, *line*=*None*)

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to *file*, which defaults to **sys.stderr**. You may replace this function with any callable by assigning to `warnings.showwarning`. *line* is a line of source code to be included in the warning message; if *line* is not supplied, **showwarning()** will try to read the line specified by *filename* and *lineno*.

warnings.formatwarning(*message*, *category*, *filename*, *lineno*, *line*=*None*)

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `formatwarning()` will try to read the line specified by *filename* and *lineno*.

warnings.filterwarnings(*action*, *message*='', *category*=*Warning*, *module*='', *lineno*=*0*, *append*=*False*)

Insert an entry into the list of warnings filter specifications. The entry is inserted at the front by default; if *append* is true, it is inserted at the end. This checks the types of the arguments, compiles the *message* and *module* regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

warnings.simplefilter(*action*, *category*=*Warning*, *lineno*=*0*, *append*=*False*)

Insert a simple entry into the list of warnings filter specifications. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

warnings.resetwarnings()

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.

Available Context Managers

class warnings.catch_warnings(*, *record*=*False*, *module*=*None*, *action*=*None*, *category*=*Warning*, *lineno*=*0*, *append*=*False*)

A context manager that copies and, upon exit, restores the warnings filter and the **`showwarning()`** function. If the *record* argument is **`False`** (the default) the context manager returns **`None`** on entry. If *record* is **`True`**, a list is returned that is progressively populated with objects as seen by a custom **`showwarning()`** function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to **`showwarning()`**.

The *module* argument takes a module that will be used instead of the module returned when you import **`warnings`** whose filter will be protected. This argument exists primarily for testing the **`warnings`** module itself.

If the *action* argument is not `None`, the remaining arguments are passed to **`simplefilter()`** as if it were called immediately on entering the context.

Note

The **`catch_warnings`** manager works by replacing and then later restoring the module's **`showwarning()`** function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.

Changed in version 3.11: Added the *action*, *category*, *lineno*, and *append* parameters.

`dataclasses` — Data Classes

Source code: Lib/dataclasses.py [https://github.com/python/cpython/tree/3.11/Lib/dataclasses.py]

This module provides a decorator and functions for automatically adding generated special methods such as **`__init__()`** and **`__repr__()`** to user-defined classes. It was originally described in **PEP 557** [https://peps.python.org/pep-0557/].

The member variables to use in these generated methods are defined using **PEP 526** [https://peps.python.org/pep-0526/] type annotations. For example, this code:

```
from dataclasses import dataclass

@dataclass
class InventoryItem:
    """Class for keeping track of an item in inventory."
    name: str
    unit_price: float
    quantity_on_hand: int = 0

    def total_cost(self) -> float:
        return self.unit_price * self.quantity_on_hand
```

will add, among other things, a **`__init__()`** that looks like:

```
def __init__(self, name: str, unit_price: float, quantit
    self.name = name
    self.unit_price = unit_price
    self.quantity_on_hand = quantity_on_hand
```

Note that this method is automatically added to the class: it is not directly specified in the `InventoryItem` definition shown above.

New in version 3.7.

Module contents

@dataclasses.dataclass(*, *init* = *True*, *repr* = *True*, *eq* = *True*, *order* = *False*, *unsafe_hash* = *False*, *frozen* = *False*, *match_args* = *True*, *kw_only* = *False*, *slots* = *False*, *weakref_slot* = *False*)

This function is a decorator that is used to add generated special methods to classes, as described below.

The **`dataclass()`** decorator examines the class to find `field`s. A `field` is defined as a class variable that has a type annotation. With two exceptions described below, nothing in **`dataclass()`** examines the type specified in the variable annotation.

The order of the fields in all of the generated methods is the order in which they appear in the class definition.

The **`dataclass()`** decorator will add various "dunder" methods to the class, described below. If any of the added methods already exist in the class, the behavior depends on the parameter, as documented below. The decorator returns the same class that it is called on; no new class is created.

If **`dataclass()`** is used just as a simple decorator with no parameters, it acts as if it has the default values documented in this signature. That is, these three uses of **`dataclass()`** are equivalent:

```
@dataclass
class C:
    ...

@dataclass()
class C:
    ...

@dataclass(init=True, repr=True, eq=True, order=Fal
```

```
            match_args=True, kw_only=False, slots=Fa
class C:
    ...
```

The parameters to **dataclass()** are:

- `init`: If true (the default), a **__init__()** method will be generated.

  If the class already defines **__init__()**, this parameter is ignored.

- `repr`: If true (the default), a **__repr__()** method will be generated. The generated repr string will have the class name and the name and repr of each field, in the order they are defined in the class. Fields that are marked as being excluded from the repr are not included. For example: `InventoryItem(name='widget', unit_price=3.0, quantity_on_hand=10).`

  If the class already defines **__repr__()**, this parameter is ignored.

- `eq`: If true (the default), an **__eq__()** method will be generated. This method compares the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type.

  If the class already defines **__eq__()**, this parameter is ignored.

- `order`: If true (the default is `False`), **__lt__()**, **__le__()**, **__gt__()**, and **__ge__()** methods will be generated. These compare the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type. If `order` is true and `eq` is false, a **ValueError** is raised.

  If the class already defines any of **__lt__()**, **__le__()**, **__gt__()**, or **__ge__()**, then

TypeError is raised.

- `unsafe_hash`: If `False` (the default), a **__hash__()** method is generated according to how `eq` and `frozen` are set.

  __hash__() is used by built-in **hash()**, and when objects are added to hashed collections such as dictionaries and sets. Having a **__hash__()** implies that instances of the class are immutable. Mutability is a complicated property that depends on the programmer's intent, the existence and behavior of **__eq__()**, and the values of the `eq` and `frozen` flags in the **dataclass()** decorator.

  By default, **dataclass()** will not implicitly add a **__hash__()** method unless it is safe to do so. Neither will it add or change an existing explicitly defined **__hash__()** method. Setting the class attribute `__hash__ = None` has a specific meaning to Python, as described in the **__hash__()** documentation.

  If **__hash__()** is not explicitly defined, or if it is set to `None`, then **dataclass()** *may* add an implicit **__hash__()** method. Although not recommended, you can force **dataclass()** to create a **__hash__()** method with `unsafe_hash=True`. This might be the case if your class is logically immutable but can nonetheless be mutated. This is a specialized use case and should be considered carefully.

  Here are the rules governing implicit creation of a **__hash__()** method. Note that you cannot both have an explicit **__hash__()** method in your dataclass and set `unsafe_hash=True`; this will result in a **TypeError**.

  If `eq` and `frozen` are both true, by default **dataclass()** will generate a **__hash__()** method for you. If `eq` is true and `frozen` is false, **__hash__()** will be set to `None`, marking it

unhashable (which it is, since it is mutable). If `eq` is false, **`__hash__()`** will be left untouched meaning the **`__hash__()`** method of the superclass will be used (if the superclass is **`object`**, this means it will fall back to id-based hashing).

- `frozen`: If true (the default is `False`), assigning to fields will generate an exception. This emulates read-only frozen instances. If **`__setattr__()`** or **`__delattr__()`** is defined in the class, then **`TypeError`** is raised. See the discussion below.

- `match_args`: If true (the default is `True`), the `__match_args__` tuple will be created from the list of parameters to the generated **`__init__()`** method (even if **`__init__()`** is not generated, see above). If false, or if `__match_args__` is already defined in the class, then `__match_args__` will not be generated.

  New in version 3.10.

- `kw_only`: If true (the default value is `False`), then all fields will be marked as keyword-only. If a field is marked as keyword-only, then the only effect is that the **`__init__()`** parameter generated from a keyword-only field must be specified with a keyword when **`__init__()`** is called. There is no effect on any other aspect of dataclasses. See the parameter glossary entry for details. Also see the **`KW_ONLY`** section.

  New in version 3.10.

- `slots`: If true (the default is `False`), **`__slots__`** attribute will be generated and new class will be returned instead of the original one. If **`__slots__`** is already defined in the class, then **`TypeError`** is raised.

  New in version 3.10.

  Changed in version 3.11: If a field name is already included in the `__slots__` of a

base class, it will not be included in the generated `__slots__` to prevent overriding them. Therefore, do not use `__slots__` to retrieve the field names of a dataclass. Use **`fields()`** instead. To be able to determine inherited slots, base class `__slots__` may be any iterable, but *not* an iterator.

- `weakref_slot`: If true (the default is `False`), add a slot named "_weakref_", which is required to make an instance weakref-able. It is an error to specify `weakref_slot=True` without also specifying `slots=True`.

  New in version 3.11.

`fields` may optionally specify a default value, using normal Python syntax:

```
@dataclass
class C:
    a: int       # 'a' has no default value
    b: int = 0   # assign a default value for 'b'
```

In this example, both `a` and `b` will be included in the added **`__init__()`** method, which will be defined as:

```
def __init__(self, a: int, b: int = 0):
```

`TypeError` will be raised if a field without a default value follows a field with a default value. This is true whether this occurs in a single class, or as a result of class inheritance.

dataclasses.field(*, *default*=*MISSING*, *default_factory*=*MISSING*, *init*=*True*, *repr*=*True*, *hash*=*None*, *compare*=*True*, *metadata*=*None*, *kw_only*=*MISSING*)

For common and simple use cases, no other functionality is required. There are, however, some dataclass features that require additional per-field information. To satisfy this need for additional information, you can replace the default field

value with a call to the provided **`field()`** function. For example:

```
@dataclass
class C:
    mylist: list[int] = field(default_factory=list)

c = C()
c.mylist += [1, 2, 3]
```

As shown above, the **`MISSING`** value is a sentinel object used to detect if some parameters are provided by the user. This sentinel is used because `None` is a valid value for some parameters with a distinct meaning. No code should directly use the **`MISSING`** value.

The parameters to **`field()`** are:

- `default`: If provided, this will be the default value for this field. This is needed because the **`field()`** call itself replaces the normal position of the default value.
- `default_factory`: If provided, it must be a zero-argument callable that will be called when a default value is needed for this field. Among other purposes, this can be used to specify fields with mutable default values, as discussed below. It is an error to specify both `default` and `default_factory`.
- `init`: If true (the default), this field is included as a parameter to the generated **`__init__()`** method.
- `repr`: If true (the default), this field is included in the string returned by the generated **`__repr__()`** method.
- `hash`: This can be a bool or `None`. If true, this field is included in the generated **`__hash__()`** method. If `None` (the default), use the value of `compare`: this would normally be the expected behavior. A field should be considered in the hash if it's used for comparisons. Setting this value to anything other than

`None` is discouraged.

One possible reason to set `hash=False` but `compare=True` would be if a field is expensive to compute a hash value for, that field is needed for equality testing, and there are other fields that contribute to the type's hash value. Even if a field is excluded from the hash, it will still be used for comparisons.

- `compare`: If true (the default), this field is included in the generated equality and comparison methods (**`__eq__()`**, **`__gt__()`**, et al.).

- `metadata`: This can be a mapping or None. None is treated as an empty dict. This value is wrapped in **`MappingProxyType()`** to make it read-only, and exposed on the **`Field`** object. It is not used at all by Data Classes, and is provided as a third-party extension mechanism. Multiple third-parties can each have their own key, to use as a namespace in the metadata.

- `kw_only`: If true, this field will be marked as keyword-only. This is used when the generated **`__init__()`** method's parameters are computed.

  New in version 3.10.

If the default value of a field is specified by a call to **`field()`**, then the class attribute for this field will be replaced by the specified `default` value. If no `default` is provided, then the class attribute will be deleted. The intent is that after the **`dataclass()`** decorator runs, the class attributes will all contain the default values for the fields, just as if the default value itself were specified. For example, after:

```
@dataclass
class C:
    x: int
    y: int = field(repr=False)
```

```
z: int = field(repr=False, default=10)
t: int = 20
```

The class attribute `C.z` will be `10`, the class attribute `C.t` will be `20`, and the class attributes `C.x` and `C.y` will not be set.

class dataclasses.Field

`Field` objects describe each defined field. These objects are created internally, and are returned by the **`fields()`** module-level method (see below). Users should never instantiate a **`Field`** object directly. Its documented attributes are:

- `name`: The name of the field.
- `type`: The type of the field.
- `default`, `default_factory`, `init`, `repr`, `hash`, `compare`, `metadata`, and `kw_only` have the identical meaning and values as they do in the **`field()`** function.

Other attributes may exist, but they are private and must not be inspected or relied on.

dataclasses.fields(*class_or_instance*)

Returns a tuple of **`Field`** objects that define the fields for this dataclass. Accepts either a dataclass, or an instance of a dataclass. Raises **`TypeError`** if not passed a dataclass or instance of one. Does not return pseudo-fields which are `ClassVar` or `InitVar`.

dataclasses.asdict(*obj*, *, *dict_factory=dict*)

Converts the dataclass `obj` to a dict (by using the factory function `dict_factory`). Each dataclass is converted to a dict of its fields, as `name: value` pairs. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with **`copy.deepcopy()`**.

Example of using **`asdict()`** on nested dataclasses:

```
@dataclass
class Point:
     x: int
     y: int

@dataclass
class C:
     mylist: list[Point]

p = Point(10, 20)
assert asdict(p) == {'x': 10, 'y': 20}

c = C([Point(0, 0), Point(10, 4)])
assert asdict(c) == {'mylist': [{'x': 0, 'y': 0}, {
```

To create a shallow copy, the following workaround may be used:

```
dict((field.name, getattr(obj, field.name)) for fie
```

`asdict()` raises **`TypeError`** if `obj` is not a dataclass instance.

dataclasses.astuple(*obj*, *, *tuple_factory*=*tuple*)

Converts the dataclass `obj` to a tuple (by using the factory function `tuple_factory`). Each dataclass is converted to a tuple of its field values. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with **`copy.deepcopy()`**.

Continuing from the previous example:

```
assert astuple(p) == (10, 20)
assert astuple(c) == ([(0, 0), (10, 4)],)
```

To create a shallow copy, the following workaround may be used:

```
tuple(getattr(obj, field.name) for field in datacla
```

astuple() raises **TypeError** if `obj` is not a dataclass instance.

dataclasses.make_dataclass(*cls_name*, *fields*, *, *bases* = *()*, *namespace* = *None*, *init* = *True*, *repr* = *True*, *eq* = *True*, *order* = *False*, *unsafe_hash* = *False*, *frozen* = *False*, *match_args* = *True*, *kw_only* = *False*, *slots* = *False*, *weakref_slot* = *False*)

Creates a new dataclass with name `cls_name`, fields as defined in `fields`, base classes as given in `bases`, and initialized with a namespace as given in `namespace`. `fields` is an iterable whose elements are each either `name`, `(name, type)`, or `(name, type, Field)`. If just `name` is supplied, `typing.Any` is used for `type`. The values of `init`, `repr`, `eq`, `order`, `unsafe_hash`, `frozen`, `match_args`, `kw_only`, `slots`, and `weakref_slot` have the same meaning as they do in **dataclass()**.

This function is not strictly required, because any Python mechanism for creating a new class with `__annotations__` can then apply the **dataclass()** function to convert that class to a dataclass. This function is provided as a convenience. For example:

```
C = make_dataclass('C',
                   [('x', int),
                     'y',
                    ('z', int, field(default=5))],
                   namespace={'add_one': lambda sel
```

Is equivalent to:

```
@dataclass
class C:
    x: int
    y: 'typing.Any'
    z: int = 5
```

```
    def add_one(self):
        return self.x + 1
```

dataclasses.replace(*obj*, */*, ***changes*)

Creates a new object of the same type as `obj`, replacing fields with values from `changes`. If `obj` is not a Data Class, raises **`TypeError`**. If values in `changes` do not specify fields, raises **`TypeError`**.

The newly returned object is created by calling the **`__init__()`** method of the dataclass. This ensures that **`__post_init__()`**, if present, is also called.

Init-only variables without default values, if any exist, must be specified on the call to **`replace()`** so that they can be passed to **`__init__()`** and **`__post_init__()`**.

It is an error for `changes` to contain any fields that are defined as having `init=False`. A **`ValueError`** will be raised in this case.

Be forewarned about how `init=False` fields work during a call to **`replace()`**. They are not copied from the source object, but rather are initialized in **`__post_init__()`**, if they're initialized at all. It is expected that `init=False` fields will be rarely and judiciously used. If they are used, it might be wise to have alternate class constructors, or perhaps a custom `replace()` (or similarly named) method which handles instance copying.

dataclasses.is_dataclass(*obj*)

Return `True` if its parameter is a dataclass or an instance of one, otherwise return `False`.

If you need to know if a class is an instance of a dataclass (and not a dataclass itself), then add a further check for `not isinstance(obj, type)`:

```
def is_dataclass_instance(obj):
    return is_dataclass(obj) and not isinstance(obj
```

dataclasses.MISSING

A sentinel value signifying a missing default or default_factory.

dataclasses.KW_ONLY

A sentinel value used as a type annotation. Any fields after a pseudo-field with the type of **KW_ONLY** are marked as keyword-only fields. Note that a pseudo-field of type **KW_ONLY** is otherwise completely ignored. This includes the name of such a field. By convention, a name of `_` is used for a **KW_ONLY** field. Keyword-only fields signify **__init__()** parameters that must be specified as keywords when the class is instantiated.

In this example, the fields `y` and `z` will be marked as keyword-only fields:

```
@dataclass
class Point:
    x: float
    _: KW_ONLY
    y: float
    z: float

p = Point(0, y=1.5, z=2.0)
```

In a single dataclass, it is an error to specify more than one field whose type is **KW_ONLY**.

New in version 3.10.

exception dataclasses.FrozenInstanceError

Raised when an implicitly defined **__setattr__()** or **__delattr__()** is called on a dataclass which was defined with `frozen=True`. It is a subclass of **AttributeError**.

Post-init processing

The generated **__init__()** code will call a method named

`__post_init__()`, if **`__post_init__()`** is defined on the class. It will normally be called as `self.__post_init__()`. However, if any `InitVar` fields are defined, they will also be passed to **`__post_init__()`** in the order they were defined in the class. If no **`__init__()`** method is generated, then **`__post_init__()`** will not automatically be called.

Among other uses, this allows for initializing field values that depend on one or more other fields. For example:

```
@dataclass
class C:
    a: float
    b: float
    c: float = field(init=False)

    def __post_init__(self):
        self.c = self.a + self.b
```

The **`__init__()`** method generated by **`dataclass()`** does not call base class **`__init__()`** methods. If the base class has an **`__init__()`** method that has to be called, it is common to call this method in a **`__post_init__()`** method:

```
@dataclass
class Rectangle:
    height: float
    width: float

@dataclass
class Square(Rectangle):
    side: float

    def __post_init__(self):
        super().__init__(self.side, self.side)
```

Note, however, that in general the dataclass-generated **`__init__()`** methods don't need to be called, since the derived dataclass will take care of initializing all fields of any base class that is a dataclass itself.

See the section below on init-only variables for ways to pass parameters to **`__post_init__()`**. Also see the warning about how **`replace()`** handles `init=False` fields.

Class variables

One of two places where **`dataclass()`** actually inspects the type of a field is to determine if a field is a class variable as defined in **PEP 526** [https://peps.python.org/pep-0526/]. It does this by checking if the type of the field is `typing.ClassVar`. If a field is a `ClassVar`, it is excluded from consideration as a field and is ignored by the dataclass mechanisms. Such `ClassVar` pseudo-fields are not returned by the module-level **`fields()`** function.

Init-only variables

The other place where **`dataclass()`** inspects a type annotation is to determine if a field is an init-only variable. It does this by seeing if the type of a field is of type `dataclasses.InitVar`. If a field is an `InitVar`, it is considered a pseudo-field called an init-only field. As it is not a true field, it is not returned by the module-level **`fields()`** function. Init-only fields are added as parameters to the generated **`__init__()`** method, and are passed to the optional **`__post_init__()`** method. They are not otherwise used by dataclasses.

For example, suppose a field will be initialized from a database, if a value is not provided when creating the class:

```
@dataclass
class C:
    i: int
    j: int | None = None
    database: InitVar[DatabaseType | None] = None

    def __post_init__(self, database):
        if self.j is None and database is not None:
            self.j = database.lookup('j')
```

```
c = C(10, database=my_database)
```

In this case, **`fields()`** will return **`Field`** objects for `i` and `j`, but not for `database`.

Frozen instances

It is not possible to create truly immutable Python objects. However, by passing `frozen=True` to the **`dataclass()`** decorator you can emulate immutability. In that case, dataclasses will add **`__setattr__()`** and **`__delattr__()`** methods to the class. These methods will raise a **`FrozenInstanceError`** when invoked.

There is a tiny performance penalty when using `frozen=True`: **`__init__()`** cannot use simple assignment to initialize fields, and must use **`object.__setattr__()`**.

Inheritance

When the dataclass is being created by the **`dataclass()`** decorator, it looks through all of the class's base classes in reverse MRO (that is, starting at **`object`**) and, for each dataclass that it finds, adds the fields from that base class to an ordered mapping of fields. After all of the base class fields are added, it adds its own fields to the ordered mapping. All of the generated methods will use this combined, calculated ordered mapping of fields. Because the fields are in insertion order, derived classes override base classes. An example:

```
@dataclass
class Base:
    x: Any = 15.0
    y: int = 0

@dataclass
class C(Base):
    z: int = 10
    x: int = 15
```

The final list of fields is, in order, `x`, `y`, `z`. The final type of `x` is `int`, as specified in class `C`.

The generated **`__init__()`** method for `C` will look like:

```
def __init__(self, x: int = 15, y: int = 0, z: int = 10)
```

Re-ordering of keyword-only parameters in `__init__()`

After the parameters needed for **`__init__()`** are computed, any keyword-only parameters are moved to come after all regular (non-keyword-only) parameters. This is a requirement of how keyword-only parameters are implemented in Python: they must come after non-keyword-only parameters.

In this example, `Base.y`, `Base.w`, and `D.t` are keyword-only fields, and `Base.x` and `D.z` are regular fields:

```
@dataclass
class Base:
    x: Any = 15.0
    _: KW_ONLY
    y: int = 0
    w: int = 1

@dataclass
class D(Base):
    z: int = 10
    t: int = field(kw_only=True, default=0)
```

The generated **`__init__()`** method for `D` will look like:

```
def __init__(self, x: Any = 15.0, z: int = 10, *, y: int
```

Note that the parameters have been re-ordered from how they appear in the list of fields: parameters derived from regular fields are followed by parameters derived from keyword-only fields.

The relative ordering of keyword-only parameters is maintained in

the re-ordered **`__init__()`** parameter list.

Default factory functions

If a **`field()`** specifies a `default_factory`, it is called with zero arguments when a default value for the field is needed. For example, to create a new instance of a list, use:

```
mylist: list = field(default_factory=list)
```

If a field is excluded from **`__init__()`** (using `init=False`) and the field also specifies `default_factory`, then the default factory function will always be called from the generated **`__init__()`** function. This happens because there is no other way to give the field an initial value.

Mutable default values

Python stores default member variable values in class attributes. Consider this example, not using dataclasses:

```
class C:
    x = []
    def add(self, element):
        self.x.append(element)

o1 = C()
o2 = C()
o1.add(1)
o2.add(2)
assert o1.x == [1, 2]
assert o1.x is o2.x
```

Note that the two instances of class `C` share the same class variable `x`, as expected.

Using dataclasses, *if* this code was valid:

```
@dataclass
```

```
class D:
    x: List = []
    def add(self, element):
        self.x += element
```

it would generate code similar to:

```
class D:
    x = []
    def __init__(self, x=x):
        self.x = x
    def add(self, element):
        self.x += element

assert D().x is D().x
```

This has the same issue as the original example using class `C`. That is, two instances of class `D` that do not specify a value for `x` when creating a class instance will share the same copy of `x`. Because dataclasses just use normal Python class creation they also share this behavior. There is no general way for Data Classes to detect this condition. Instead, the **`dataclass()`** decorator will raise a **`TypeError`** if it detects an unhashable default parameter. The assumption is that if a value is unhashable, it is mutable. This is a partial solution, but it does protect against many common errors.

Using default factory functions is a way to create new instances of mutable types as default values for fields:

```
@dataclass
class D:
    x: list = field(default_factory=list)

assert D().x is not D().x
```

Changed in version 3.11: Instead of looking for and disallowing objects of type `list`, `dict`, or `set`, unhashable objects are now not allowed as default values. Unhashability is used to approximate mutability.

Descriptor-typed fields

Fields that are assigned descriptor objects as their default value have the following special behaviors:

- The value for the field passed to the dataclass's `__init__` method is passed to the descriptor's `__set__` method rather than overwriting the descriptor object.
- Similarly, when getting or setting the field, the descriptor's `__get__` or `__set__` method is called rather than returning or overwriting the descriptor object.
- To determine whether a field contains a default value, `dataclasses` will call the descriptor's `__get__` method using its class access form (i.e. `descriptor.__get__(obj=None, type=cls)`. If the descriptor returns a value in this case, it will be used as the field's default. On the other hand, if the descriptor raises **`AttributeError`** in this situation, no default value will be provided for the field.

```
class IntConversionDescriptor:
    def __init__(self, *, default):
        self._default = default

    def __set_name__(self, owner, name):
        self._name = "_" + name

    def __get__(self, obj, type):
        if obj is None:
            return self._default

        return getattr(obj, self._name, self._default)

    def __set__(self, obj, value):
        setattr(obj, self._name, int(value))

@dataclass
class InventoryItem:
    quantity_on_hand: IntConversionDescriptor = IntConve
```

```
i = InventoryItem()
print(i.quantity_on_hand)   # 100
i.quantity_on_hand = 2.5    # calls __set__ with 2.5
print(i.quantity_on_hand)   # 2
```

Note that if a field is annotated with a descriptor type, but is not assigned a descriptor object as its default value, the field will act like a normal field.

`contextlib` — Utilities for `with`-statement contexts

Source code: Lib/contextlib.py [https://github.com/python/cpython/tree/3.11/Lib/contextlib.py]

This module provides utilities for common tasks involving the **`with`** statement. For more information see also Context Manager Types and With Statement Context Managers.

Utilities

Functions and classes provided:

class contextlib.AbstractContextManager

An abstract base class for classes that implement **`object.__enter__()`** and **`object.__exit__()`**. A default implementation for **`object.__enter__()`** is provided which returns `self` while **`object.__exit__()`** is an abstract method which by default returns `None`. See also the definition of Context Manager Types.

New in version 3.6.

class contextlib.AbstractAsyncContextManager

An abstract base class for classes that implement **`object.__aenter__()`** and **`object.__aexit__()`**. A default implementation for **`object.__aenter__()`** is provided which returns `self` while **`object.__aexit__()`** is an abstract method which by default returns `None`. See also the definition of Asynchronous Context Managers.

New in version 3.7.

@contextlib.contextmanager

This function is a decorator that can be used to define a factory function for **with** statement context managers, without needing to create a class or separate **__enter__()** and **__exit__()** methods.

While many objects natively support use in with statements, sometimes a resource needs to be managed that isn't a context manager in its own right, and doesn't implement a `close()` method for use with `contextlib.closing`

An abstract example would be the following to ensure correct resource management:

```
from contextlib import contextmanager

@contextmanager
def managed_resource(*args, **kwds):
    # Code to acquire resource, e.g.:
    resource = acquire_resource(*args, **kwds)
    try:
        yield resource
    finally:
        # Code to release resource, e.g.:
        release_resource(resource)
```

The function can then be used like this:

```
>>> with managed_resource(timeout=3600) as resource
...     # Resource is released at the end of this b
...     # even if code in the block raises an excep
```

The function being decorated must return a generator-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the **with** statement's **as** clause, if any.

At the point where the generator yields, the block nested in the **with** statement is executed. The generator is then resumed after the block is exited. If an unhandled exception

occurs in the block, it is reraised inside the generator at the point where the yield occurred. Thus, you can use a **try**…**except**…**finally** statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the **with** statement that the exception has been handled, and execution will resume with the statement immediately following the **with** statement.

contextmanager() uses **ContextDecorator** so the context managers it creates can be used as decorators as well as in **with** statements. When used as a decorator, a new generator instance is implicitly created on each function call (this allows the otherwise "one-shot" context managers created by **contextmanager()** to meet the requirement that context managers support multiple invocations in order to be used as decorators).

Changed in version 3.2: Use of **ContextDecorator**.

@contextlib.asynccontextmanager

Similar to **contextmanager()**, but creates an asynchronous context manager.

This function is a decorator that can be used to define a factory function for **async with** statement asynchronous context managers, without needing to create a class or separate **__aenter__()** and **__aexit__()** methods. It must be applied to an asynchronous generator function.

A simple example:

```
from contextlib import asynccontextmanager

@asynccontextmanager
async def get_connection():
```

```
    conn = await acquire_db_connection()
    try:
        yield conn
    finally:
        await release_db_connection(conn)

async def get_all_users():
    async with get_connection() as conn:
        return conn.query('SELECT ...')
```

New in version 3.7.

Context managers defined with **`asynccontextmanager()`** can be used either as decorators or with **`async with`** statements:

```
import time
from contextlib import asynccontextmanager

@asynccontextmanager
async def timeit():
    now = time.monotonic()
    try:
        yield
    finally:
        print(f'it took {time.monotonic() - n

@timeit()
async def main():
    # ... async code ...
```

When used as a decorator, a new generator instance is implicitly created on each function call. This allows the otherwise “one-shot” context managers created by **`asynccontextmanager()`** to meet the requirement that context managers support multiple invocations in order to be used as decorators.

Changed in version 3.10: Async context managers created with **`asynccontextmanager()`** can be used as decorators.

contextlib.closing(*thing*)

Return a context manager that closes *thing* upon completion of the block. This is basically equivalent to:

```
from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
        thing.close()
```

And lets you write code like this:

```
from contextlib import closing
from urllib.request import urlopen

with closing(urlopen('https://www.python.org')) as
    for line in page:
        print(line)
```

without needing to explicitly close `page`. Even if an error occurs, `page.close()` will be called when the **`with`** block is exited.

contextlib.aclosing(*thing*)

Return an async context manager that calls the `aclose()` method of *thing* upon completion of the block. This is basically equivalent to:

```
from contextlib import asynccontextmanager

@asynccontextmanager
async def aclosing(thing):
    try:
```

```
            yield thing
        finally:
            await thing.aclose()
```

Significantly, `aclosing()` supports deterministic cleanup of async generators when they happen to exit early by **`break`** or an exception. For example:

```
from contextlib import aclosing

async with aclosing(my_generator()) as values:
    async for value in values:
        if value == 42:
            break
```

This pattern ensures that the generator's async exit code is executed in the same context as its iterations (so that exceptions and context variables work as expected, and the exit code isn't run after the lifetime of some task it depends on).

New in version 3.10.

contextlib.nullcontext(*enter_result=None*)

Return a context manager that returns *enter_result* from `__enter__`, but otherwise does nothing. It is intended to be used as a stand-in for an optional context manager, for example:

```
def myfunction(arg, ignore_exceptions=False):
    if ignore_exceptions:
        # Use suppress to ignore all exceptions.
        cm = contextlib.suppress(Exception)
    else:
        # Do not ignore any exceptions, cm has no e
        cm = contextlib.nullcontext()
    with cm:
        # Do something
```

An example using *enter_result*:

```
def process_file(file_or_path):
    if isinstance(file_or_path, str):
        # If string, open file
        cm = open(file_or_path)
    else:
        # Caller is responsible for closing file
        cm = nullcontext(file_or_path)

    with cm as file:
        # Perform processing on the file
```

It can also be used as a stand-in for asynchronous context managers:

```
async def send_http(session=None):
    if not session:
        # If no http session, create it with aiohtt
        cm = aiohttp.ClientSession()
    else:
        # Caller is responsible for closing the ses
        cm = nullcontext(session)

    async with cm as session:
        # Send http requests with session
```

New in version 3.7.

Changed in version 3.10: asynchronous context manager support was added.

contextlib.suppress(**exceptions*)

Return a context manager that suppresses any of the specified exceptions if they occur in the body of a **`with`** statement and then resumes execution with the first statement following the end of the **`with`** statement.

As with any other mechanism that completely suppresses exceptions, this context manager should be used only to cover very specific errors where silently continuing with program

execution is known to be the right thing to do.

For example:

```
from contextlib import suppress

with suppress(FileNotFoundError):
    os.remove('somefile.tmp')

with suppress(FileNotFoundError):
    os.remove('someotherfile.tmp')
```

This code is equivalent to:

```
try:
    os.remove('somefile.tmp')
except FileNotFoundError:
    pass

try:
    os.remove('someotherfile.tmp')
except FileNotFoundError:
    pass
```

This context manager is reentrant.

New in version 3.4.

contextlib.redirect_stdout(*new_target*)

Context manager for temporarily redirecting **`sys.stdout`** to another file or file-like object.

This tool adds flexibility to existing functions or classes whose output is hardwired to stdout.

For example, the output of **`help()`** normally is sent to *sys.stdout*. You can capture that output in a string by redirecting the output to an **`io.StringIO`** object. The replacement stream is returned from the `__enter__` method and so is available as the target of the **`with`** statement:

```
with redirect_stdout(io.StringIO()) as f:
    help(pow)
s = f.getvalue()
```

To send the output of `help()` to a file on disk, redirect the output to a regular file:

```
with open('help.txt', 'w') as f:
    with redirect_stdout(f):
        help(pow)
```

To send the output of `help()` to *sys.stderr*:

```
with redirect_stdout(sys.stderr):
    help(pow)
```

Note that the global side effect on `sys.stdout` means that this context manager is not suitable for use in library code and most threaded applications. It also has no effect on the output of subprocesses. However, it is still a useful approach for many utility scripts.

This context manager is reentrant.

New in version 3.4.

contextlib.redirect_stderr(*new_target*)

Similar to `redirect_stdout()` but redirecting `sys.stderr` to another file or file-like object.

This context manager is reentrant.

New in version 3.5.

contextlib.chdir(*path*)

Non parallel-safe context manager to change the current working directory. As this changes a global state, the working directory, it is not suitable for use in most threaded or async contexts. It is also not suitable for most non-linear code execution, like generators, where the program execution is

temporarily relinquished – unless explicitly desired, you should not yield when this context manager is active.

This is a simple wrapper around **`chdir()`**, it changes the current working directory upon entering and restores the old one on exit.

This context manager is reentrant.

New in version 3.11.

class contextlib.ContextDecorator

A base class that enables a context manager to also be used as a decorator.

Context managers inheriting from `ContextDecorator` have to implement `__enter__` and `__exit__` as normal. `__exit__` retains its optional exception handling even when used as a decorator.

`ContextDecorator` is used by **`contextmanager()`**, so you get this functionality automatically.

Example of `ContextDecorator`:

```
from contextlib import ContextDecorator

class mycontext(ContextDecorator):
    def __enter__(self):
        print('Starting')
        return self

    def __exit__(self, *exc):
        print('Finishing')
        return False
```

The class can then be used like this:

```
>>> @mycontext()
... def function():
...     print('The bit in the middle')
```

```
...
>>> function()
Starting
The bit in the middle
Finishing

>>> with mycontext():
...     print('The bit in the middle')
...
Starting
The bit in the middle
Finishing
```

This change is just syntactic sugar for any construct of the following form:

```
def f():
    with cm():
        # Do stuff
```

`ContextDecorator` lets you instead write:

```
@cm()
def f():
    # Do stuff
```

It makes it clear that the `cm` applies to the whole function, rather than just a piece of it (and saving an indentation level is nice, too).

Existing context managers that already have a base class can be extended by using `ContextDecorator` as a mixin class:

```
from contextlib import ContextDecorator

class mycontext(ContextBaseClass, ContextDecorator):
    def __enter__(self):
        return self

    def __exit__(self, *exc):
```

```
        return False
```

Note

As the decorated function must be able to be called multiple times, the underlying context manager must support use in multiple **with** statements. If this is not the case, then the original construct with the explicit **with** statement inside the function should be used.

New in version 3.2.

class contextlib.AsyncContextDecorator

Similar to **ContextDecorator** but only for asynchronous functions.

Example of `AsyncContextDecorator`:

```
from asyncio import run
from contextlib import AsyncContextDecorator

class mycontext(AsyncContextDecorator):
    async def __aenter__(self):
        print('Starting')
        return self

    async def __aexit__(self, *exc):
        print('Finishing')
        return False
```

The class can then be used like this:

```
>>> @mycontext()
... async def function():
...     print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
```

```
Finishing

>>> async def function():
...     async with mycontext():
...         print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
Finishing
```

New in version 3.10.

class contextlib.ExitStack

A context manager that is designed to make it easy to programmatically combine other context managers and cleanup functions, especially those that are optional or otherwise driven by input data.

For example, a set of files may easily be handled in a single with statement as follows:

```
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for f
    # All opened files will automatically be closed
    # the with statement, even if attempts to open
    # in the list raise an exception
```

The **__enter__()** method returns the **ExitStack** instance, and performs no additional operations.

Each instance maintains a stack of registered callbacks that are called in reverse order when the instance is closed (either explicitly or implicitly at the end of a **with** statement). Note that callbacks are *not* invoked implicitly when the context stack instance is garbage collected.

This stack model is used so that context managers that acquire their resources in their __init__ method (such as file objects) can be handled correctly.

Since registered callbacks are invoked in the reverse order of registration, this ends up behaving as if multiple nested **with** statements had been used with the registered set of callbacks. This even extends to exception handling - if an inner callback suppresses or replaces an exception, then outer callbacks will be passed arguments based on that updated state.

This is a relatively low level API that takes care of the details of correctly unwinding the stack of exit callbacks. It provides a suitable foundation for higher level context managers that manipulate the exit stack in application specific ways.

New in version 3.3.

enter_context(*cm*)

Enters a new context manager and adds its **__exit__()** method to the callback stack. The return value is the result of the context manager's own **__enter__()** method.

These context managers may suppress exceptions just as they normally would if used directly as part of a **with** statement.

Changed in version 3.11: Raises **TypeError** instead of **AttributeError** if *cm* is not a context manager.

push(*exit*)

Adds a context manager's **__exit__()** method to the callback stack.

As `__enter__` is *not* invoked, this method can be used to cover part of an **__enter__()** implementation with a context manager's own **__exit__()** method.

If passed an object that is not a context manager, this method assumes it is a callback with the same signature as a context manager's **__exit__()** method and adds it directly to the callback stack.

By returning true values, these callbacks can suppress exceptions the same way context manager **`__exit__()`** methods can.

The passed in object is returned from the function, allowing this method to be used as a function decorator.

callback(*callback*, */*, **args*, ***kwds*)

Accepts an arbitrary callback function and arguments and adds it to the callback stack.

Unlike the other methods, callbacks added this way cannot suppress exceptions (as they are never passed the exception details).

The passed in callback is returned from the function, allowing this method to be used as a function decorator.

pop_all()

Transfers the callback stack to a fresh **`ExitStack`** instance and returns it. No callbacks are invoked by this operation - instead, they will now be invoked when the new stack is closed (either explicitly or implicitly at the end of a **`with`** statement).

For example, a group of files can be opened as an “all or nothing” operation as follows:

```
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) f
    # Hold onto the close method, but don't cal
    close_files = stack.pop_all().close
    # If opening any file fails, all previously
    # closed automatically. If all files are op
    # they will remain open even after the with
    # close_files() can then be invoked explici
```

close()

Immediately unwinds the callback stack, invoking callbacks in the reverse order of registration. For any context managers and exit callbacks registered, the arguments passed in will indicate that no exception occurred.

class contextlib.AsyncExitStack

An asynchronous context manager, similar to **ExitStack**, that supports combining both synchronous and asynchronous context managers, as well as having coroutines for cleanup logic.

The **close()** method is not implemented, **aclose()** must be used instead.

coroutine enter_async_context(*cm*)

Similar to **enter_context()** but expects an asynchronous context manager.

Changed in version 3.11: Raises **TypeError** instead of **AttributeError** if *cm* is not an asynchronous context manager.

push_async_exit(*exit*)

Similar to **push()** but expects either an asynchronous context manager or a coroutine function.

push_async_callback(*callback*, */*, **args*, ***kwds*)

Similar to **callback()** but expects a coroutine function.

coroutine aclose()

Similar to **close()** but properly handles awaitables.

Continuing the example for **asynccontextmanager()**:

```
async with AsyncExitStack() as stack:
```

```
        connections = [await stack.enter_async_context(
            for i in range(5)]
        # All opened connections will automatically be
        # the async with statement, even if attempts to
        # later in the list raise an exception.
```

New in version 3.7.

Examples and Recipes

This section describes some examples and recipes for making effective use of the tools provided by **contextlib**.

Supporting a variable number of context managers

The primary use case for **ExitStack** is the one given in the class documentation: supporting a variable number of context managers and other cleanup operations in a single **with** statement. The variability may come from the number of context managers needed being driven by user input (such as opening a user specified collection of files), or from some of the context managers being optional:

```
with ExitStack() as stack:
    for resource in resources:
        stack.enter_context(resource)
    if need_special_resource():
        special = acquire_special_resource()
        stack.callback(release_special_resource, special
    # Perform operations that use the acquired resources
```

As shown, **ExitStack** also makes it quite easy to use **with** statements to manage arbitrary resources that don't natively support the context management protocol.

Catching exceptions from **__enter__** methods

It is occasionally desirable to catch exceptions from an `__enter__` method implementation, *without* inadvertently catching exceptions

from the **`with`** statement body or the context manager's `__exit__` method. By using **`ExitStack`** the steps in the context management protocol can be separated slightly in order to allow this:

```
stack = ExitStack()
try:
    x = stack.enter_context(cm)
except Exception:
    # handle __enter__ exception
else:
    with stack:
        # Handle normal case
```

Actually needing to do this is likely to indicate that the underlying API should be providing a direct resource management interface for use with **`try`**/**`except`**/**`finally`** statements, but not all APIs are well designed in that regard. When a context manager is the only resource management API provided, then **`ExitStack`** can make it easier to handle various situations that can't be handled directly in a **`with`** statement.

Cleaning up in an **`__enter__`** implementation

As noted in the documentation of **`ExitStack.push()`**, this method can be useful in cleaning up an already allocated resource if later steps in the **`__enter__()`** implementation fail.

Here's an example of doing this for a context manager that accepts resource acquisition and release functions, along with an optional validation function, and maps them to the context management protocol:

```
from contextlib import contextmanager, AbstractContextMa

class ResourceManager(AbstractContextManager):

    def __init__(self, acquire_resource, release_resourc
        self.acquire_resource = acquire_resource
        self.release_resource = release_resource
```

```
        if check_resource_ok is None:
            def check_resource_ok(resource):
                return True
        self.check_resource_ok = check_resource_ok

    @contextmanager
    def _cleanup_on_error(self):
        with ExitStack() as stack:
            stack.push(self)
            yield
            # The validation check passed and didn't rai
            # Accordingly, we want to keep the resource,
            # back to our caller
            stack.pop_all()

    def __enter__(self):
        resource = self.acquire_resource()
        with self._cleanup_on_error():
            if not self.check_resource_ok(resource):
                msg = "Failed validation for {!r}"
                raise RuntimeError(msg.format(resource))
        return resource

    def __exit__(self, *exc_details):
        # We don't need to duplicate any of our resource
        self.release_resource()
```

Replacing any use of `try-finally` and flag variables

A pattern you will sometimes see is a `try-finally` statement with a flag variable to indicate whether or not the body of the `finally` clause should be executed. In its simplest form (that can't already be handled just by using an `except` clause instead), it looks something like this:

```
cleanup_needed = True
try:
    result = perform_operation()
    if result:
```

```
        cleanup_needed = False
finally:
    if cleanup_needed:
        cleanup_resources()
```

As with any `try` statement based code, this can cause problems for development and review, because the setup code and the cleanup code can end up being separated by arbitrarily long sections of code.

`ExitStack` makes it possible to instead register a callback for execution at the end of a `with` statement, and then later decide to skip executing that callback:

```
from contextlib import ExitStack

with ExitStack() as stack:
    stack.callback(cleanup_resources)
    result = perform_operation()
    if result:
        stack.pop_all()
```

This allows the intended cleanup up behaviour to be made explicit up front, rather than requiring a separate flag variable.

If a particular application uses this pattern a lot, it can be simplified even further by means of a small helper class:

```
from contextlib import ExitStack

class Callback(ExitStack):
    def __init__(self, callback, /, *args, **kwds):
        super().__init__()
        self.callback(callback, *args, **kwds)

    def cancel(self):
        self.pop_all()

with Callback(cleanup_resources) as cb:
    result = perform_operation()
```

```
    if result:
        cb.cancel()
```

If the resource cleanup isn't already neatly bundled into a standalone function, then it is still possible to use the decorator form of **`ExitStack.callback()`** to declare the resource cleanup in advance:

```
from contextlib import ExitStack

with ExitStack() as stack:
    @stack.callback
    def cleanup_resources():
        ...
    result = perform_operation()
    if result:
        stack.pop_all()
```

Due to the way the decorator protocol works, a callback function declared this way cannot take any parameters. Instead, any resources to be released must be accessed as closure variables.

Using a context manager as a function decorator

`ContextDecorator` makes it possible to use a context manager in both an ordinary `with` statement and also as a function decorator.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context manager for the task, inheriting from **`ContextDecorator`** provides both capabilities in a single definition:

```
from contextlib import ContextDecorator
import logging

logging.basicConfig(level=logging.INFO)

class track_entry_and_exit(ContextDecorator):
    def __init__(self, name):
```

```
        self.name = name

    def __enter__(self):
        logging.info('Entering: %s', self.name)

    def __exit__(self, exc_type, exc, exc_tb):
        logging.info('Exiting: %s', self.name)
```

Instances of this class can be used as both a context manager:

```
with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()
```

And also as a function decorator:

```
@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()
```

Note that there is one additional limitation when using context managers as function decorators: there's no way to access the return value of **`__enter__()`**. If that value is needed, then it is still necessary to use an explicit `with` statement.

See also

PEP 343 [https://peps.python.org/pep-0343/] - The "with" statement
: The specification, background, and examples for the Python **`with`** statement.

Single use, reusable and reentrant context managers

Most context managers are written in a way that means they can only be used effectively in a **`with`** statement once. These single use

context managers must be created afresh each time they're used - attempting to use them a second time will trigger an exception or otherwise not work correctly.

This common limitation means that it is generally advisable to create context managers directly in the header of the **`with`** statement where they are used (as shown in all of the usage examples above).

Files are an example of effectively single use context managers, since the first **`with`** statement will close the file, preventing any further IO operations using that file object.

Context managers created using **`contextmanager()`** are also single use context managers, and will complain about the underlying generator failing to yield if an attempt is made to use them a second time:

```
>>> from contextlib import contextmanager
>>> @contextmanager
... def singleuse():
...     print("Before")
...     yield
...     print("After")
...

```

Reentrant context managers

More sophisticated context managers may be "reentrant". These context managers can not only be used in multiple `with` statements, but may also be used *inside* a `with` statement that is already using the same context manager.

`threading.RLock` is an example of a reentrant context manager, as are `suppress()`, `redirect_stdout()`, and `chdir()`. Here's a very simple example of reentrant use:

```
>>> from contextlib import redirect_stdout
>>> from io import StringIO
>>> stream = StringIO()
>>> write_to_stream = redirect_stdout(stream)
>>> with write_to_stream:
...     print("This is written to the stream rather thar
...     with write_to_stream:
...         print("This is also written to the stream")
...
>>> print("This is written directly to stdout")
This is written directly to stdout
>>> print(stream.getvalue())
This is written to the stream rather than stdout
This is also written to the stream
```

Real world examples of reentrancy are more likely to involve multiple functions calling each other and hence be far more complicated than this example.

Note also that being reentrant is *not* the same thing as being thread safe. `redirect_stdout()`, for example, is definitely not thread safe, as it makes a global modification to the system state by binding `sys.stdout` to a different stream.

Reusable context managers

Distinct from both single use and reentrant context managers are "reusable" context managers (or, to be completely explicit, "reusable, but not reentrant" context managers, since reentrant context managers are also reusable). These context managers support being used multiple times, but will fail (or otherwise not

work correctly) if the specific context manager instance has already been used in a containing with statement.

threading.Lock is an example of a reusable, but not reentrant, context manager (for a reentrant lock, it is necessary to use **threading.RLock** instead).

Another example of a reusable, but not reentrant, context manager is **ExitStack**, as it invokes *all* currently registered callbacks when leaving any with statement, regardless of where those callbacks were added:

```
>>> from contextlib import ExitStack
>>> stack = ExitStack()
>>> with stack:
...     stack.callback(print, "Callback: from first cont
...     print("Leaving first context")
...
Leaving first context
Callback: from first context
>>> with stack:
...     stack.callback(print, "Callback: from second cor
...     print("Leaving second context")
...
Leaving second context
Callback: from second context
>>> with stack:
...     stack.callback(print, "Callback: from outer cont
...     with stack:
...         stack.callback(print, "Callback: from inner
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Callback: from outer context
Leaving outer context
```

As the output from the example shows, reusing a single stack object across multiple with statements works correctly, but attempting to

nest them will cause the stack to be cleared at the end of the innermost with statement, which is unlikely to be desirable behaviour.

Using separate **`ExitStack`** instances instead of reusing a single instance avoids that problem:

```
>>> from contextlib import ExitStack
>>> with ExitStack() as outer_stack:
...     outer_stack.callback(print, "Callback: from oute
...     with ExitStack() as inner_stack:
...         inner_stack.callback(print, "Callback: from
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Leaving outer context
Callback: from outer context
```

`abc` — Abstract Base Classes

Source code: Lib/abc.py [https://github.com/python/cpython/tree/3.11/Lib/abc.py]

This module provides the infrastructure for defining abstract base classes (ABCs) in Python, as outlined in **PEP 3119** [https://peps.python.org/pep-3119/]; see the PEP for why this was added to Python. (See also **PEP 3141** [https://peps.python.org/pep-3141/] and the `numbers` module regarding a type hierarchy for numbers based on ABCs.)

The `collections` module has some concrete classes that derive from ABCs; these can, of course, be further derived. In addition, the `collections.abc` submodule has some ABCs that can be used to test whether a class or instance provides a particular interface, for example, if it is hashable or if it is a mapping.

This module provides the metaclass `ABCMeta` for defining ABCs and a helper class `ABC` to alternatively define ABCs through inheritance:

class abc.ABC

A helper class that has `ABCMeta` as its metaclass. With this class, an abstract base class can be created by simply deriving from `ABC` avoiding sometimes confusing metaclass usage, for example:

```
from abc import ABC

class MyABC(ABC):
    pass
```

Note that the type of `ABC` is still `ABCMeta`, therefore inheriting from `ABC` requires the usual precautions regarding metaclass usage, as multiple inheritance may lead to

metaclass conflicts. One may also define an abstract base class by passing the metaclass keyword and using **ABCMeta** directly, for example:

```
from abc import ABCMeta

class MyABC(metaclass=ABCMeta):
    pass
```

New in version 3.4.

class abc.ABCMeta

Metaclass for defining Abstract Base Classes (ABCs).

Use this metaclass to create an ABC. An ABC can be subclassed directly, and then acts as a mix-in class. You can also register unrelated concrete classes (even built-in classes) and unrelated ABCs as "virtual subclasses" – these and their descendants will be considered subclasses of the registering ABC by the built-in **issubclass()** function, but the registering ABC won't show up in their MRO (Method Resolution Order) nor will method implementations defined by the registering ABC be callable (not even via **super()**). 1

Classes created with a metaclass of **ABCMeta** have the following method:

register(*subclass*)

Register *subclass* as a "virtual subclass" of this ABC. For example:

```
from abc import ABC

class MyABC(ABC):
    pass

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance((), MyABC)
```

Changed in version 3.3: Returns the registered subclass, to allow usage as a class decorator.

Changed in version 3.4: To detect calls to **`register()`**, you can use the **`get_cache_token()`** function.

You can also override this method in an abstract base class:

subclasshook(*subclass*)

(Must be defined as a class method.)

Check whether *subclass* is considered a subclass of this ABC. This means that you can customize the behavior of `issubclass` further without the need to call **`register()`** on every class you want to consider a subclass of the ABC. (This class method is called from the **`__subclasscheck__()`** method of the ABC.)

This method should return `True`, `False` or `NotImplemented`. If it returns `True`, the *subclass* is considered a subclass of this ABC. If it returns `False`, the *subclass* is not considered a subclass of this ABC, even if it would normally be one. If it returns `NotImplemented`, the subclass check is continued with the usual mechanism.

For a demonstration of these concepts, look at this example ABC definition:

```
class Foo:
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)

class MyIterable(ABC):

    @abstractmethod
```

```
        def __iter__(self):
            while False:
                yield None

        def get_iterator(self):
            return self.__iter__()

        @classmethod
        def __subclasshook__(cls, C):
            if cls is MyIterable:
                if any("__iter__" in B.__dict__ for B i
                    return True
            return NotImplemented

MyIterable.register(Foo)
```

The ABC `MyIterable` defines the standard iterable method, **`__iter__()`**, as an abstract method. The implementation given here can still be called from subclasses. The **`get_iterator()`** method is also part of the `MyIterable` abstract base class, but it does not have to be overridden in non-abstract derived classes.

The **`__subclasshook__()`** class method defined here says that any class that has an **`__iter__()`** method in its **`__dict__`** (or in that of one of its base classes, accessed via the **`__mro__`** list) is considered a `MyIterable` too.

Finally, the last line makes `Foo` a virtual subclass of `MyIterable`, even though it does not define an **`__iter__()`** method (it uses the old-style iterable protocol, defined in terms of **`__len__()`** and **`__getitem__()`**). Note that this will not make `get_iterator` available as a method of `Foo`, so it is provided separately.

The **`abc`** module also provides the following decorator:

@abc.abstractmethod

A decorator indicating abstract methods.

Using this decorator requires that the class's metaclass is **ABCMeta** or is derived from it. A class that has a metaclass derived from **ABCMeta** cannot be instantiated unless all of its abstract methods and properties are overridden. The abstract methods can be called using any of the normal 'super' call mechanisms. **abstractmethod()** may be used to declare abstract methods for properties and descriptors.

Dynamically adding abstract methods to a class, or attempting to modify the abstraction status of a method or class once it is created, are only supported using the **update_abstractmethods()** function. The **abstractmethod()** only affects subclasses derived using regular inheritance; "virtual subclasses" registered with the ABC's **register()** method are not affected.

When **abstractmethod()** is applied in combination with other method descriptors, it should be applied as the innermost decorator, as shown in the following usage examples:

```
class C(ABC):
    @abstractmethod
    def my_abstract_method(self, arg1):
        ...
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg2):
        ...
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg3):
        ...

    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
    @my_abstract_property.setter
    @abstractmethod
```

```
    def my_abstract_property(self, val):
        ...

    @abstractmethod
    def _get_x(self):
        ...
    @abstractmethod
    def _set_x(self, val):
        ...
    x = property(_get_x, _set_x)
```

In order to correctly interoperate with the abstract base class machinery, the descriptor must identify itself as abstract using **`__isabstractmethod__`**. In general, this attribute should be `True` if any of the methods used to compose the descriptor are abstract. For example, Python's built-in **`property`** does the equivalent of:

```
class Descriptor:
    ...
    @property
    def __isabstractmethod__(self):
        return any(getattr(f, '__isabstractmethod__
                   f in (self._fget, self._fset, se
```

Note

Unlike Java abstract methods, these abstract methods may have an implementation. This implementation can be called via the **`super()`** mechanism from the class that overrides it. This could be useful as an end-point for a super-call in a framework that uses cooperative multiple-inheritance.

The **`abc`** module also supports the following legacy decorators:

@abc.abstractclassmethod

New in version 3.2.

Deprecated since version 3.3: It is now possible to use **classmethod** with **abstractmethod()**, making this decorator redundant.

A subclass of the built-in **classmethod()**, indicating an abstract classmethod. Otherwise it is similar to **abstractmethod()**.

This special case is deprecated, as the **classmethod()** decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg):
        ...
```

@abc.abstractstaticmethod

New in version 3.2.

Deprecated since version 3.3: It is now possible to use **staticmethod** with **abstractmethod()**, making this decorator redundant.

A subclass of the built-in **staticmethod()**, indicating an abstract staticmethod. Otherwise it is similar to **abstractmethod()**.

This special case is deprecated, as the **staticmethod()** decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg):
        ...
```

@abc.abstractproperty

Deprecated since version 3.3: It is now possible to use **property**, **property.getter()**, **property.setter()** and **property.deleter()** with **abstractmethod()**, making this decorator redundant.

A subclass of the built-in **property()**, indicating an abstract property.

This special case is deprecated, as the **property()** decorator is now correctly identified as abstract when applied to an abstract method:

```
class C(ABC):
    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
```

The above example defines a read-only property; you can also define a read-write abstract property by appropriately marking one or more of the underlying methods as abstract:

```
class C(ABC):
    @property
    def x(self):
        ...

    @x.setter
    @abstractmethod
    def x(self, val):
        ...
```

If only some components are abstract, only those components need to be updated to create a concrete property in a subclass:

```
class D(C):
    @C.x.setter
    def x(self, val):
        ...
```

The **abc** module also provides the following functions:

abc.get_cache_token()

Returns the current abstract base class cache token.

The token is an opaque object (that supports equality testing) identifying the current version of the abstract base class cache for virtual subclasses. The token changes with every call to **ABCMeta.register()** on any ABC.

New in version 3.4.

abc.update_abstractmethods(*cls*)

A function to recalculate an abstract class's abstraction status. This function should be called if a class's abstract methods have been implemented or changed after it was created. Usually, this function should be called from within a class decorator.

Returns *cls*, to allow usage as a class decorator.

If *cls* is not an instance of **ABCMeta**, does nothing.

Note

This function assumes that *cls*'s superclasses are already updated. It does not update any subclasses.

New in version 3.10.

Footnotes

1

C++ programmers should note that Python's virtual base class concept is not the same as C++'s.

`atexit` — Exit handlers

The `atexit` module defines functions to register and unregister cleanup functions. Functions thus registered are automatically executed upon normal interpreter termination. `atexit` runs these functions in the *reverse* order in which they were registered; if you register `A`, `B`, and `C`, at interpreter termination time they will be run in the order `C`, `B`, `A`.

Note: The functions registered via this module are not called when the program is killed by a signal not handled by Python, when a Python fatal internal error is detected, or when `os._exit()` is called.

Changed in version 3.7: When used with C-API subinterpreters, registered functions are local to the interpreter they were registered in.

atexit.register(*func*, **args*, ***kwargs*)

Register *func* as a function to be executed at termination. Any optional arguments that are to be passed to *func* must be passed as arguments to `register()`. It is possible to register the same function and arguments more than once.

At normal program termination (for instance, if `sys.exit()` is called or the main module's execution completes), all functions registered are called in last in, first out order. The assumption is that lower level modules will normally be imported before higher level modules and thus must be cleaned up later.

If an exception is raised during execution of the exit handlers, a traceback is printed (unless `SystemExit` is raised) and the exception information is saved. After all exit handlers have had a chance to run, the last exception to be raised is re-

raised.

This function returns *func*, which makes it possible to use it as a decorator.

atexit.unregister(*func*)

Remove *func* from the list of functions to be run at interpreter shutdown. `unregister()` silently does nothing if *func* was not previously registered. If *func* has been registered more than once, every occurrence of that function in the `atexit` call stack will be removed. Equality comparisons (==) are used internally during unregistration, so function references do not need to have matching identities.

See also

Module `readline`
Useful example of `atexit` to read and write `readline` history files.

`atexit` Example

The following simple example demonstrates how a module can initialize a counter from a file when it is imported and save the counter's updated value automatically when the program terminates without relying on the application making an explicit call into this module at termination.

```
try:
    with open('counterfile') as infile:
        _count = int(infile.read())
except FileNotFoundError:
    _count = 0

def incrcounter(n):
    global _count
    _count = _count + n
```

```
def savecounter():
    with open('counterfile', 'w') as outfile:
        outfile.write('%d' % _count)

import atexit

atexit.register(savecounter)
```

Positional and keyword arguments may also be passed to **`register()`** to be passed along to the registered function when it is called:

```
def goodbye(name, adjective):
    print('Goodbye %s, it was %s to meet you.' % (name,

import atexit

atexit.register(goodbye, 'Donny', 'nice')
# or:
atexit.register(goodbye, adjective='nice', name='Donny')
```

Usage as a decorator:

```
import atexit

@atexit.register
def goodbye():
    print('You are now leaving the Python sector.')
```

This only works with functions that can be called without arguments.

`traceback` — Print or retrieve a stack traceback

Source code: Lib/traceback.py [https://github.com/python/cpython/tree/3.11/Lib/traceback.py]

This module provides a standard interface to extract, format and print stack traces of Python programs. It exactly mimics the behavior of the Python interpreter when it prints a stack trace. This is useful when you want to print stack traces under program control, such as in a "wrapper" around the interpreter.

The module uses traceback objects — this is the object type that is stored in the `sys.last_traceback` variable and returned as the third item from `sys.exc_info()`.

The module defines the following functions:

traceback.print_tb(*tb*, *limit*=*None*, *file*=*None*)

Print up to *limit* stack trace entries from traceback object *tb* (starting from the caller's frame) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. If *file* is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open file or file-like object to receive the output.

Changed in version 3.5: Added negative *limit* support.

traceback.print_exception(*exc*, /, [*value*, *tb*,]*limit*=*None*, *file*=*None*, *chain*=*True*)

Print exception information and stack trace entries from traceback object *tb* to *file*. This differs from `print_tb()` in the following ways:

- if *tb* is not `None`, it prints a header `Traceback (most recent call last):`
- it prints the exception type and *value* after the stack trace

- if *type(value)* is **`SyntaxError`** and *value* has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.

Since Python 3.10, instead of passing *value* and *tb*, an exception object can be passed as the first argument. If *value* and *tb* are provided, the first argument is ignored in order to provide backwards compatibility.

The optional *limit* argument has the same meaning as for **`print_tb()`**. If *chain* is true (the default), then chained exceptions (the **`__cause__`** or **`__context__`** attributes of the exception) will be printed as well, like the interpreter itself does when printing an unhandled exception.

Changed in version 3.5: The *etype* argument is ignored and inferred from the type of *value*.

Changed in version 3.10: The *etype* parameter has been renamed to *exc* and is now positional-only.

traceback.print_exc(*limit=None*, *file=None*, *chain=True*)

This is a shorthand for `print_exception(*sys.exc_info(), limit, file, chain)`.

traceback.print_last(*limit=None*, *file=None*, *chain=True*)

This is a shorthand for `print_exception(sys.last_type, sys.last_value, sys.last_traceback, limit, file, chain)`. In general it will work only after an exception has reached an interactive prompt (see **`sys.last_type`**).

traceback.print_stack(*f=None*, *limit=None*, *file=None*)

Print up to *limit* stack trace entries (starting from the invocation point) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. The optional *f* argument can be used to specify an alternate stack frame to start. The optional *file* argument has the same meaning as for **`print_tb()`**.

Changed in version 3.5: Added negative *limit* support.

traceback.extract_tb(*tb*, *limit=None*)

Return a **`StackSummary`** object representing a list of "pre-processed" stack trace entries extracted from the traceback object *tb*. It is useful for alternate formatting of stack traces. The optional *limit* argument has the same meaning as for **`print_tb()`**. A "pre-processed" stack trace entry is a **`FrameSummary`** object containing attributes **`filename`**, **`lineno`**, **`name`**, and **`line`** representing the information that is usually printed for a stack trace. The **`line`** is a string with leading and trailing whitespace stripped; if the source is not available it is `None`.

traceback.extract_stack(*f=None*, *limit=None*)

Extract the raw traceback from the current stack frame. The return value has the same format as for **`extract_tb()`**. The optional *f* and *limit* arguments have the same meaning as for **`print_stack()`**.

traceback.format_list(*extracted_list*)

Given a list of tuples or **`FrameSummary`** objects as returned by **`extract_tb()`** or **`extract_stack()`**, return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not `None`.

traceback.format_exception_only(*exc*, */*[, *value*])

Format the exception part of a traceback using an exception value such as given by `sys.last_value`. The return value is a list of strings, each ending in a newline. Normally, the list contains a single string; however, for **`SyntaxError`** exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. The message indicating which exception occurred is the always last string in the list.

Since Python 3.10, instead of passing *value*, an exception object can be passed as the first argument. If *value* is provided, the first argument is ignored in order to provide backwards compatibility.

Changed in version 3.10: The *etype* parameter has been renamed to *exc* and is now positional-only.

traceback.format_exception(*exc*, */*, [*value*, *tb*,]*limit*=*None*, *chain*=*True*)

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to **`print_exception()`**. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does **`print_exception()`**.

Changed in version 3.5: The *etype* argument is ignored and inferred from the type of *value*.

Changed in version 3.10: This function's behavior and signature were modified to match **`print_exception()`**.

traceback.format_exc(*limit*=*None*, *chain*=*True*)

This is like `print_exc(limit)` but returns a string instead of printing to a file.

traceback.format_tb(*tb*, *limit*=*None*)

A shorthand for `format_list(extract_tb(tb,`

`limit))`.

traceback.format_stack(*f*=*None*, *limit*=*None*)

A shorthand for `format_list(extract_stack(f, limit))`.

traceback.clear_frames(*tb*)

Clears the local variables of all the stack frames in a traceback *tb* by calling the **`clear()`** method of each frame object.

New in version 3.4.

traceback.walk_stack(*f*)

Walk a stack following `f.f_back` from the given frame, yielding the frame and line number for each frame. If *f* is `None`, the current stack is used. This helper is used with **`StackSummary.extract()`**.

New in version 3.5.

traceback.walk_tb(*tb*)

Walk a traceback following `tb_next` yielding the frame and line number for each frame. This helper is used with **`StackSummary.extract()`**.

New in version 3.5.

The module also defines the following classes:

`TracebackException` Objects

New in version 3.5.

`TracebackException` objects are created from actual exceptions to capture data for later printing in a lightweight fashion.

class traceback.TracebackException(*exc_type*, *exc_value*,

exc_traceback, ***, *limit=None*, *lookup_lines=True*, *capture_locals=False*, *compact=False*)

Capture an exception for later rendering. *limit*, *lookup_lines* and *capture_locals* are as for the **StackSummary** class.

If *compact* is true, only data that is required by **TracebackException**'s `format` method is saved in the class attributes. In particular, the `__context__` field is calculated only if `__cause__` is `None` and `__suppress_context__` is false.

Note that when locals are captured, they are also shown in the traceback.

cause

A **TracebackException** of the original `__cause__`.

context

A **TracebackException** of the original `__context__`.

_suppress_context_

The `__suppress_context__` value from the original exception.

notes

The `__notes__` value from the original exception, or `None` if the exception does not have any notes. If it is not `None` is it formatted in the traceback after the exception string.

New in version 3.11.

stack

A **StackSummary** representing the traceback.

exc_type

The class of the original traceback.

filename

For syntax errors - the file name where the error occurred.

lineno

For syntax errors - the line number where the error occurred.

text

For syntax errors - the text where the error occurred.

offset

For syntax errors - the offset into the text where the error occurred.

msg

For syntax errors - the compiler error message.

classmethod from_exception(*exc*, *, *limit=None*, *lookup_lines=True*, *capture_locals=False*)

Capture an exception for later rendering. *limit*, *lookup_lines* and *capture_locals* are as for the **`StackSummary`** class.

Note that when locals are captured, they are also shown in the traceback.

print(*, *file=None*, *chain=True*)

Print to *file* (default `sys.stderr`) the exception information returned by **`format()`**.

New in version 3.11.

format(*, *chain=True*)

Format the exception.

If *chain* is not `True`, `__cause__` and `__context__` will not be formatted.

The return value is a generator of strings, each ending in a newline and some containing internal newlines. **`print_exception()`** is a wrapper around this method which just prints the lines to a file.

The message indicating which exception occurred is always the last string in the output.

format_exception_only()

Format the exception part of the traceback.

The return value is a generator of strings, each ending in a newline.

Normally, the generator emits a single string; however, for **`SyntaxError`** exceptions, it emits several lines that (when printed) display detailed information about where the syntax error occurred.

The message indicating which exception occurred is always the last string in the output.

Changed in version 3.10: Added the *compact* parameter.

`StackSummary` Objects

New in version 3.5.

`StackSummary` objects represent a call stack ready for formatting.

class traceback.StackSummary

classmethod extract(*frame_gen*, *, *limit*=*None*, *lookup_lines*=*True*, *capture_locals*=*False*)

Construct a **`StackSummary`** object from a frame generator (such as is returned by **`walk_stack()`** or

walk_tb()).

If *limit* is supplied, only this many frames are taken from *frame_gen*. If *lookup_lines* is `False`, the returned **FrameSummary** objects will not have read their lines in yet, making the cost of creating the **StackSummary** cheaper (which may be valuable if it may not actually get formatted). If *capture_locals* is `True` the local variables in each **FrameSummary** are captured as object representations.

classmethod from_list(*a_list*)

Construct a **StackSummary** object from a supplied list of **FrameSummary** objects or old-style list of tuples. Each tuple should be a 4-tuple with filename, lineno, name, line as the elements.

format()

Returns a list of strings ready for printing. Each string in the resulting list corresponds to a single frame from the stack. Each string ends in a newline; the strings may contain internal newlines as well, for those items with source text lines.

For long sequences of the same frame and line, the first few repetitions are shown, followed by a summary line stating the exact number of further repetitions.

Changed in version 3.6: Long sequences of repeated frames are now abbreviated.

format_frame_summary(*frame_summary*)

Returns a string for printing one of the frames involved in the stack. This method is called for each **FrameSummary** object to be printed by **StackSummary.format()**. If it returns `None`, the frame is omitted from the output.

New in version 3.11.

`FrameSummary` Objects

New in version 3.5.

A `FrameSummary` object represents a single frame in a traceback.

class traceback.FrameSummary(*filename*, *lineno*, *name*, *lookup_line=True*, *locals=None*, *line=None*)

Represent a single frame in the traceback or stack that is being formatted or printed. It may optionally have a stringified version of the frames locals included in it. If *lookup_line* is `False`, the source code is not looked up until the `FrameSummary` has the `line` attribute accessed (which also happens when casting it to a tuple). `line` may be directly provided, and will prevent line lookups happening at all. *locals* is an optional local variable dictionary, and if supplied the variable representations are stored in the summary for later display.

Traceback Examples

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the `code` module.

```
import sys, traceback

def run_user_code(envdir):
    source = input(">>> ")
    try:
        exec(source, envdir)
    except Exception:
        print("Exception in user code:")
        print("-"*60)
        traceback.print_exc(file=sys.stdout)
        print("-"*60)
```

```
envdir = {}
while True:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```
import sys, traceback

def lumberjack():
    bright_side_of_life()

def bright_side_of_life():
    return tuple()[0]

try:
    lumberjack()
except IndexError:
    exc_type, exc_value, exc_traceback = sys.exc_info()
    print("*** print_tb:")
    traceback.print_tb(exc_traceback, limit=1, file=sys.
    print("*** print_exception:")
    traceback.print_exception(exc_value, limit=2, file=s
    print("*** print_exc:")
    traceback.print_exc(limit=2, file=sys.stdout)
    print("*** format_exc, first and last line:")
    formatted_lines = traceback.format_exc().splitlines(
    print(formatted_lines[0])
    print(formatted_lines[-1])
    print("*** format_exception:")
    print(repr(traceback.format_exception(exc_value)))
    print("*** extract_tb:")
    print(repr(traceback.extract_tb(exc_traceback)))
    print("*** format_tb:")
    print(repr(traceback.format_tb(exc_traceback)))
    print("*** tb_lineno:", exc_traceback.tb_lineno)
```

The output for the example would look similar to this:

```
*** print_tb:
  File "<doctest...>", line 10, in <module>
    lumberjack()
*** print_exception:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_life()
IndexError: tuple index out of range
*** print_exc:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_life()
IndexError: tuple index out of range
*** format_exc, first and last line:
Traceback (most recent call last):
IndexError: tuple index out of range
*** format_exception:
['Traceback (most recent call last):\n',
 '  File "<doctest default[0]>", line 10, in <module>\n
 '  File "<doctest default[0]>", line 4, in lumberjack\r
 '  File "<doctest default[0]>", line 7, in bright_side_
 'IndexError: tuple index out of range\n']
*** extract_tb:
[<FrameSummary file <doctest...>, line 10 in <module>>,
 <FrameSummary file <doctest...>, line 4 in lumberjack>,
 <FrameSummary file <doctest...>, line 7 in bright_side_
*** format_tb:
['  File "<doctest default[0]>", line 10, in <module>\n
 '  File "<doctest default[0]>", line 4, in lumberjack\r
 '  File "<doctest default[0]>", line 7, in bright_side_
*** tb_lineno: 10
```

The following example shows the different ways to print and format the stack:

```
>>> import traceback
>>> def another_function():
...     lumberstack()
...
>>> def lumberstack():
...     traceback.print_stack()
...     print(repr(traceback.extract_stack()))
...     print(repr(traceback.format_stack()))
...
>>> another_function()
  File "<doctest>", line 10, in <module>
    another_function()
  File "<doctest>", line 3, in another_function
    lumberstack()
  File "<doctest>", line 6, in lumberstack
    traceback.print_stack()
[('<doctest>', 10, '<module>', 'another_function()'),
 ('<doctest>', 3, 'another_function', 'lumberstack()'),
 ('<doctest>', 7, 'lumberstack', 'print(repr(traceback.e
['  File "<doctest>", line 10, in <module>\n    another_
 '  File "<doctest>", line 3, in another_function\n    l
 '  File "<doctest>", line 8, in lumberstack\n    print(
```

This last example demonstrates the final few formatting functions:

```
>>> import traceback
>>> traceback.format_list([('spam.py', 3, '<module>', 's
...                        ('eggs.py', 42, 'eggs', 'retu
['  File "spam.py", line 3, in <module>\n    spam.eggs()
 '  File "eggs.py", line 42, in eggs\n    return "bacon"
>>> an_error = IndexError('tuple index out of range')
>>> traceback.format_exception_only(type(an_error), an_e
['IndexError: tuple index out of range\n']
```

`__future__` — Future statement definitions

Source code: Lib/_future_.py [https://github.com/python/cpython/tree/3.11/Lib/_future_.py]

`__future__` is a real module, and serves three purposes:

- To avoid confusing existing tools that analyze import statements and expect to find the modules they're importing.
- To ensure that future statements run under releases prior to 2.1 at least yield runtime exceptions (the import of `__future__` will fail, because there was no module of that name prior to 2.1).
- To document when incompatible changes were introduced, and when they will be — or were — made mandatory. This is a form of executable documentation, and can be inspected programmatically via importing `__future__` and examining its contents.

Each statement in `__future__.py` is of the form:

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease
                       CompilerFlag)
```

where, normally, *OptionalRelease* is less than *MandatoryRelease*, and both are 5-tuples of the same form as `sys.version_info`:

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
 PY_MINOR_VERSION, # the 1; an int
 PY_MICRO_VERSION, # the 0; an int
 PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "fi
 PY_RELEASE_SERIAL # the 3; an int
)
```

OptionalRelease records the first release in which the feature was accepted.

In the case of a *MandatoryRelease* that has not yet occurred, *MandatoryRelease* predicts the release in which the feature will become part of the language.

Else *MandatoryRelease* records when the feature became part of the language; in releases at or after that, modules no longer need a future statement to use the feature in question, but may continue to use such imports.

MandatoryRelease may also be `None`, meaning that a planned feature got dropped.

Instances of class **`_Feature`** have two corresponding methods, **`getOptionalRelease()`** and **`getMandatoryRelease()`**.

CompilerFlag is the (bitfield) flag that should be passed in the fourth argument to the built-in function **`compile()`** to enable the feature in dynamically compiled code. This flag is stored in the **`compiler_flag`** attribute on **`_Feature`** instances.

No feature description will ever be deleted from **`__future__`**. Since its introduction in Python 2.1 the following features have found their way into the language using this mechanism:

feature	optional in	mandatory in	effect
nested_scopes	2.1.0b1	2.2	*PEP 227: Statically Nested Scopes*
generators	2.2.0a1	2.3	*PEP 255: Simple Generators*
division	2.2.0a2	3.0	*PEP 238: Changing the Division Operator*
absolute_import	2.5.0a1	3.0	*PEP 328: Imports: Multi-Line and Absolute/Relative*
with_statement	2.5.0a1	2.6	*PEP 343: The "with" Statement*
print_function	2.6.0a2	3.0	*PEP 3105: Make print a function*
unicode_literals	2.6.0a2	3.0	*PEP 3112: Bytes literals in Python 3000*
generator_stop	3.5.0b1	3.7	*PEP 479: StopIteration handling inside generators*
annotations	3.7.0b1	TBD[1]	*PEP 563: Postponed evaluation of annotations*

[1] `from __future__ import annotations` was previously scheduled to become mandatory in Python 3.10, but the

Python Steering Council twice decided to delay the change (announcement for Python 3.10 [https://mail.python.org/archives/list/python-dev@python.org/message/CLVXXPQ2T2LQ5MP2Y53VVQFCXYWQJHKZ/]; announcement for Python 3.11 [https://mail.python.org/archives/list/python-dev@python.org/message/VIZEBX5EYMSYIJNDBF6DMUMZOCWHARSO/]). No final decision has been made yet. See also **PEP 563** [https://peps.python.org/pep-0563/] and **PEP 649** [https://peps.python.org/pep-0649/].

: How the compiler treats future imports.

gc — Garbage Collector interface

This module provides an interface to the optional garbage collector. It provides the ability to disable the collector, tune the collection frequency, and set debugging options. It also provides access to unreachable objects that the collector found but cannot free. Since the collector supplements the reference counting already used in Python, you can disable the collector if you are sure your program does not create reference cycles. Automatic collection can be disabled by calling `gc.disable()`. To debug a leaking program call `gc.set_debug(gc.DEBUG_LEAK)`. Notice that this includes `gc.DEBUG_SAVEALL`, causing garbage-collected objects to be saved in gc.garbage for inspection.

The **gc** module provides the following functions:

gc.enable()

Enable automatic garbage collection.

gc.disable()

Disable automatic garbage collection.

gc.isenabled()

Return `True` if automatic collection is enabled.

gc.collect(*generation*=*2*)

With no arguments, run a full collection. The optional argument *generation* may be an integer specifying which generation to collect (from 0 to 2). A **ValueError** is raised if the generation number is invalid. The number of unreachable objects found is returned.

The free lists maintained for a number of built-in types are cleared whenever a full collection or collection of the highest generation (2) is run. Not all items in some free lists may be freed due to the particular implementation, in particular **`float`**.

gc.set_debug(*flags*)

Set the garbage collection debugging flags. Debugging information will be written to `sys.stderr`. See below for a list of debugging flags which can be combined using bit operations to control debugging.

gc.get_debug()

Return the debugging flags currently set.

gc.get_objects(*generation=None*)

Returns a list of all objects tracked by the collector, excluding the list returned. If *generation* is not None, return only the objects tracked by the collector that are in that generation.

Changed in version 3.8: New *generation* parameter.

Raises an auditing event `gc.get_objects` with argument `generation`.

gc.get_stats()

Return a list of three per-generation dictionaries containing collection statistics since interpreter start. The number of keys may change in the future, but currently each dictionary will contain the following items:

- `collections` is the number of times this generation was collected;
- `collected` is the total number of objects collected inside this generation;
- `uncollectable` is the total number of objects which were found to be uncollectable (and were therefore moved to the **`garbage`** list) inside this generation.

New in version 3.4.

gc.set_threshold(*threshold0*[, *threshold1*[, *threshold2*]])

Set the garbage collection thresholds (the collection frequency). Setting *threshold0* to zero disables collection.

The GC classifies objects into three generations depending on how many collection sweeps they have survived. New objects are placed in the youngest generation (generation `0`). If an object survives a collection it is moved into the next older generation. Since generation `2` is the oldest generation, objects in that generation remain there after a collection. In order to decide when to run, the collector keeps track of the number object allocations and deallocations since the last collection. When the number of allocations minus the number of deallocations exceeds *threshold0*, collection starts. Initially only generation `0` is examined. If generation `0` has been examined more than *threshold1* times since generation `1` has been examined, then generation `1` is examined as well. With the third generation, things are a bit more complicated, see Collecting the oldest generation [https://devguide.python.org/garbage_collector/#collecting-the-oldest-generation] for more information.

gc.get_count()

Return the current collection counts as a tuple of `(count0, count1, count2)`.

gc.get_threshold()

Return the current collection thresholds as a tuple of `(threshold0, threshold1, threshold2)`.

gc.get_referrers(**objs*)

Return the list of objects that directly refer to any of objs. This function will only locate those containers which support garbage collection; extension types which do refer to other objects but do not support garbage collection will not be found.

Note that objects which have already been dereferenced, but which live in cycles and have not yet been collected by the garbage collector can be listed among the resulting referrers. To get only currently live objects, call **`collect()`** before calling **`get_referrers()`**.

Warning

Care must be taken when using objects returned by **`get_referrers()`** because some of them could still be under construction and hence in a temporarily invalid state. Avoid using **`get_referrers()`** for any purpose other than debugging.

Raises an auditing event `gc.get_referrers` with argument `objs`.

gc.get_referents(**objs*)

Return a list of objects directly referred to by any of the arguments. The referents returned are those objects visited by the arguments' C-level **`tp_traverse`** methods (if any), and may not be all objects actually directly reachable. **`tp_traverse`** methods are supported only by objects that support garbage collection, and are only required to visit objects that may be involved in a cycle. So, for example, if an integer is directly reachable from an argument, that integer object may or may not appear in the result list.

Raises an auditing event `gc.get_referents` with argument `objs`.

gc.is_tracked(*obj*)

Returns `True` if the object is currently tracked by the garbage collector, `False` otherwise. As a general rule, instances of atomic types aren't tracked and instances of non-atomic types (containers, user-defined objects…) are. However, some type-specific optimizations can be present in order to suppress the garbage collector footprint of simple instances (e.g. dicts containing only atomic keys and values):

```
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```

New in version 3.1.

gc.is_finalized(*obj*)

Returns `True` if the given object has been finalized by the garbage collector, `False` otherwise.

```
>>> x = None
>>> class Lazarus:
...     def __del__(self):
...         global x
...         x = self
...
>>> lazarus = Lazarus()
>>> gc.is_finalized(lazarus)
False
>>> del lazarus
>>> gc.is_finalized(x)
True
```

New in version 3.9.

gc.freeze()

Freeze all the objects tracked by gc - move them to a permanent generation and ignore all the future collections. This can be used before a POSIX fork() call to make the gc

copy-on-write friendly or to speed up collection. Also collection before a POSIX fork() call may free pages for future allocation which can cause copy-on-write too so it's advised to disable gc in parent process and freeze before fork and enable gc in child process.

New in version 3.7.

gc.unfreeze()

Unfreeze the objects in the permanent generation, put them back into the oldest generation.

New in version 3.7.

gc.get_freeze_count()

Return the number of objects in the permanent generation.

New in version 3.7.

The following variables are provided for read-only access (you can mutate the values but should not rebind them):

gc.garbage

A list of objects which the collector found to be unreachable but could not be freed (uncollectable objects). Starting with Python 3.4, this list should be empty most of the time, except when using instances of C extension types with a non-`NULL` `tp_del` slot.

If **`DEBUG_SAVEALL`** is set, then all unreachable objects will be added to this list rather than freed.

Changed in version 3.2: If this list is non-empty at interpreter shutdown, a **`ResourceWarning`** is emitted, which is silent by default. If **`DEBUG_UNCOLLECTABLE`** is set, in addition all uncollectable objects are printed.

Changed in version 3.4: Following **PEP 442** [https://peps.python.org/pep-0442/], objects with a **`__del__()`** method don't end up in **`gc.garbage`** anymore.

gc.callbacks

A list of callbacks that will be invoked by the garbage collector before and after collection. The callbacks will be called with two arguments, *phase* and *info*.

phase can be one of two values:

"start": The garbage collection is about to start.

"stop": The garbage collection has finished.

info is a dict providing more information for the callback. The following keys are currently defined:

"generation": The oldest generation being collected.

"collected": When *phase* is "stop", the number of objects successfully collected.

"uncollectable": When *phase* is "stop", the number of objects that could not be collected and were put in **garbage**.

Applications can add their own callbacks to this list. The primary use cases are:

Gathering statistics about garbage collection, such as how often various generations are collected, and how long the collection takes.

Allowing applications to identify and clear their own uncollectable types when they appear in **garbage**.

New in version 3.3.

The following constants are provided for use with **set_debug()**:

gc.DEBUG_STATS

Print statistics during collection. This information can be useful when tuning the collection frequency.

gc.DEBUG_COLLECTABLE

Print information on collectable objects found.

gc.DEBUG_UNCOLLECTABLE

Print information of uncollectable objects found (objects which are not reachable but cannot be freed by the collector). These objects will be added to the `garbage` list.

Changed in version 3.2: Also print the contents of the **`garbage`** list at interpreter shutdown, if it isn't empty.

gc.DEBUG_SAVEALL

When set, all unreachable objects found will be appended to *garbage* rather than being freed. This can be useful for debugging a leaking program.

gc.DEBUG_LEAK

The debugging flags necessary for the collector to print information about a leaking program (equal to `DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_SAVEALL`).

`inspect` — Inspect live objects

Source code: Lib/inspect.py [https://github.com/python/cpython/tree/3.11/Lib/inspect.py]

The `inspect` module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.

Types and members

The `getmembers()` function retrieves the members of an object such as a class or module. The functions whose names begin with "is" are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes (see Import-related module attributes for module attributes):

Type	Attribute	Description
class	__doc__	documentation string
	__name__	name with which this class was defined
	__qualname__	qualified name
	__module__	name of module in which this class was defined
method	__doc__	documentation string
	__name__	name with which this method was defined
	__qualname__	qualified name
	__func__	function object containing implementation of method

__self__	instance to which this method is bound, or `None`
__module__	name of module in which this method was defined
__doc__	documentation string
__name__	name with which this function was defined
__qualname__	qualified name
__code__	code object containing compiled function bytecode
__defaults__	tuple of any default values for positional or keyword parameters
__kwdefaults__	mapping of any default values for keyword-only parameters
__globals__	global namespace in which this function was defined
__builtins__	builtins namespace
__annotations__	mapping of parameters names to annotations; `"return"` key is reserved for return annotations.
__module__	name of module in which this function was defined
f_back	next outer frame object (this frame's caller)
f_builtins	builtins namespace seen by this frame
f_code	code object being executed in this frame
f_globals	global namespace seen by this frame
f_lasti	index of last attempted instruction in bytecode
f_lineno	current line number in Python source code
f_locals	local namespace seen by this frame
f_trace	tracing function for this frame, or `None`
co_argcount	number of arguments (not including keyword only arguments, * or ** args)
co_code	string of raw compiled bytecode
co_cellvars	tuple of names of cell variables (referenced by containing scopes)
co_consts	tuple of constants used in the bytecode
co_filename	name of file in which this code object was created
co_firstlineno	number of first line in Python source code
co_flags	bitflags of `CO_*` flags, read more here
co_lnotab	encoded mapping of line numbers to bytecode indices
co_freevars	tuple of names of free variables (referenced via a function's closure)
co_posonlyargcount	number of positional only arguments
co_kwonlyargcount	number of keyword only arguments (not including ** arg)
co_name	name with which this code object was defined
co_qualname	fully qualified name with which this code object was defined

co_names	tuple of names other than arguments and function locals
co_nlocals	number of local variables
co_stacksize	virtual machine stack space required
co_varnames	tuple of names of arguments and local variables
gen.gi_code	code
gen.gi_frame	frame
gen.gi_running	is the generator running?
gen.gi_yieldfrom	object being iterated by `yield from`, or `None`
coro.cr_await	object being awaited on, or `None`
coro.cr_code	code
coro.cr_frame	frame
coro.cr_running	is the coroutine running?
coro.cr_origin	where coroutine was created, or `None`. See **`sys.set_coroutine_origin_tracking_depth()`**
method.__doc__	documentation string
method.__name__	original name of this function or method
method.__qualname__	qualified name
method.__self__	instance to which a method is bound, or `None`

Changed in version 3.5: Add `__qualname__` and `gi_yieldfrom` attributes to generators.

The `__name__` attribute of generators is now set from the function name, instead of the code name, and it can now be modified.

Changed in version 3.7: Add `cr_origin` attribute to coroutines.

Changed in version 3.10: Add `__builtins__` attribute to functions.

inspect.getmembers(*object*[, *predicate*])

Return all the members of an object in a list of `(name, value)` pairs sorted by name. If the optional *predicate* argument—which will be called with the `value` object of each member—is supplied, only members for which the predicate returns a true value are included.

Note

getmembers() will only return class attributes defined in the metaclass when the argument is a class and those attributes have been listed in the metaclass' custom **__dir__()**.

inspect.getmembers_static(*object*[, *predicate*])

Return all the members of an object in a list of `(name, value)` pairs sorted by name without triggering dynamic lookup via the descriptor protocol, _getattr_ or _getattribute_. Optionally, only return members that satisfy a given predicate.

Note

getmembers_static() may not be able to retrieve all members that getmembers can fetch (like dynamically created attributes) and may find members that getmembers can't (like descriptors that raise AttributeError). It can also return descriptor objects instead of instance members in some cases.

New in version 3.11.

inspect.getmodulename(*path*)

Return the name of the module named by the file *path*, without including the names of enclosing packages. The file extension is checked against all of the entries in **importlib.machinery.all_suffixes()**. If it matches, the final path component is returned with the extension removed. Otherwise, `None` is returned.

Note that this function *only* returns a meaningful name for actual Python modules - paths that potentially refer to Python packages will still return `None`.

Changed in version 3.3: The function is based directly on

importlib.

inspect.ismodule(*object*)

Return `True` if the object is a module.

inspect.isclass(*object*)

Return `True` if the object is a class, whether built-in or created in Python code.

inspect.ismethod(*object*)

Return `True` if the object is a bound method written in Python.

inspect.isfunction(*object*)

Return `True` if the object is a Python function, which includes functions created by a lambda expression.

inspect.isgeneratorfunction(*object*)

Return `True` if the object is a Python generator function.

Changed in version 3.8: Functions wrapped in **functools.partial()** now return `True` if the wrapped function is a Python generator function.

inspect.isgenerator(*object*)

Return `True` if the object is a generator.

inspect.iscoroutinefunction(*object*)

Return `True` if the object is a coroutine function (a function defined with an **async def** syntax).

New in version 3.5.

Changed in version 3.8: Functions wrapped in **functools.partial()** now return `True` if the wrapped function is a coroutine function.

inspect.iscoroutine(*object*)

Return `True` if the object is a coroutine created by an **`async def`** function.

New in version 3.5.

inspect.isawaitable(*object*)

Return `True` if the object can be used in **`await`** expression.

Can also be used to distinguish generator-based coroutines from regular generators:

```
def gen():
    yield
@types.coroutine
def gen_coro():
    yield

assert not isawaitable(gen())
assert isawaitable(gen_coro())
```

New in version 3.5.

inspect.isasyncgenfunction(*object*)

Return `True` if the object is an asynchronous generator function, for example:

```
>>> async def agen():
...     yield 1
...
>>> inspect.isasyncgenfunction(agen)
True
```

New in version 3.6.

Changed in version 3.8: Functions wrapped in **`functools.partial()`** now return `True` if the wrapped function is a asynchronous generator function.

inspect.isasyncgen(*object*)

Return `True` if the object is an asynchronous generator iterator created by an asynchronous generator function.

New in version 3.6.

inspect.istraceback(*object*)

Return `True` if the object is a traceback.

inspect.isframe(*object*)

Return `True` if the object is a frame.

inspect.iscode(*object*)

Return `True` if the object is a code.

inspect.isbuiltin(*object*)

Return `True` if the object is a built-in function or a bound built-in method.

inspect.ismethodwrapper(*object*)

Return `True` if the type of object is a **`MethodWrapperType`**.

These are instances of **`MethodWrapperType`**, such as **`__str__()`**, **`__eq__()`** and **`__repr__()`**.

New in version 3.11.

inspect.isroutine(*object*)

Return `True` if the object is a user-defined or built-in function or method.

inspect.isabstract(*object*)

Return `True` if the object is an abstract base class.

inspect.ismethoddescriptor(*object*)

Return `True` if the object is a method descriptor, but not if **`ismethod()`**, **`isclass()`**, **`isfunction()`** or **`isbuiltin()`** are true.

This, for example, is true of `int.__add__`. An object passing this test has a **`__get__()`** method but not a **`__set__()`** method, but beyond that the set of attributes varies. A **`__name__`** attribute is usually sensible, and **`__doc__`** often is.

Methods implemented via descriptors that also pass one of the other tests return `False` from the **`ismethoddescriptor()`** test, simply because the other tests promise more – you can, e.g., count on having the **`__func__`** attribute (etc) when an object passes **`ismethod()`**.

inspect.isdatadescriptor(*object*)

Return `True` if the object is a data descriptor.

Data descriptors have a **`__set__`** or a **`__delete__`** method. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have **`__name__`** and **`__doc__`** attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

inspect.isgetsetdescriptor(*object*)

Return `True` if the object is a getset descriptor.

CPython implementation detail: getsets are attributes defined in extension modules via **`PyGetSetDef`** structures. For Python implementations without such types, this method will always return `False`.

inspect.ismemberdescriptor(*object*)

Return `True` if the object is a member descriptor.

CPython implementation detail: Member descriptors are attributes defined in extension modules via **PyMemberDef** structures. For Python implementations without such types, this method will always return `False`.

Retrieving source code

inspect.getdoc(*object*)

Get the documentation string for an object, cleaned up with **cleandoc()**. If the documentation string for an object is not provided and the object is a class, a method, a property or a descriptor, retrieve the documentation string from the inheritance hierarchy. Return `None` if the documentation string is invalid or missing.

Changed in version 3.5: Documentation strings are now inherited if not overridden.

inspect.getcomments(*object*)

Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module). If the object's source code is unavailable, return `None`. This could happen if the object has been defined in C or the interactive shell.

inspect.getfile(*object*)

Return the name of the (text or binary) file in which an object was defined. This will fail with a **TypeError** if the object is a built-in module, class, or function.

inspect.getmodule(*object*)

Try to guess which module an object was defined in. Return `None` if the module cannot be determined.

inspect.getsourcefile(*object*)

Return the name of the Python source file in which an object

was defined or `None` if no way can be identified to get the source. This will fail with a **`TypeError`** if the object is a built-in module, class, or function.

inspect.getsourcelines(*object*)

Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An **`OSError`** is raised if the source code cannot be retrieved.

Changed in version 3.3: **`OSError`** is raised instead of **`IOError`**, now an alias of the former.

inspect.getsource(*object*)

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An **`OSError`** is raised if the source code cannot be retrieved.

Changed in version 3.3: **`OSError`** is raised instead of **`IOError`**, now an alias of the former.

inspect.cleandoc(*doc*)

Clean up indentation from docstrings that are indented to line up with blocks of code.

All leading whitespace is removed from the first line. Any leading whitespace that can be uniformly removed from the second line onwards is removed. Empty lines at the beginning and end are subsequently removed. Also, all tabs are expanded to spaces.

Introspecting callables with the Signature object

New in version 3.3.

The Signature object represents the call signature of a callable object and its return annotation. To retrieve a Signature object, use the **signature()** function.

inspect.signature(*callable*, ***, *follow_wrapped=True*, *globals=None*, *locals=None*, *eval_str=False*)

Return a **Signature** object for the given `callable`:

```
>>> from inspect import signature
>>> def foo(a, *, b:int, **kwargs):
...     pass

>>> sig = signature(foo)

>>> str(sig)
'(a, *, b:int, **kwargs)'

>>> str(sig.parameters['b'])
'b:int'

>>> sig.parameters['b'].annotation
<class 'int'>
```

Accepts a wide range of Python callables, from plain functions and classes to **functools.partial()** objects.

For objects defined in modules using stringized annotations (`from __future__ import annotations`), **signature()** will attempt to automatically un-stringize the annotations using **inspect.get_annotations()**. The `global`, `locals`, and `eval_str` parameters are passed into **inspect.get_annotations()** when resolving the annotations; see the documentation for **inspect.get_annotations()** for instructions on how to use these parameters.

Raises **ValueError** if no signature can be provided, and **TypeError** if that type of object is not supported. Also, if the

annotations are stringized, and `eval_str` is not false, the `eval()` call(s) to un-stringize the annotations could potentially raise any kind of exception.

A slash(*/*) in the signature of a function denotes that the parameters prior to it are positional-only. For more info, see the FAQ entry on positional-only parameters.

New in version 3.5: `follow_wrapped` parameter. Pass `False` to get a signature of `callable` specifically (`callable.__wrapped__` will not be used to unwrap decorated callables.)

New in version 3.10: `globals`, `locals`, and `eval_str` parameters.

Note

Some callables may not be introspectable in certain implementations of Python. For example, in CPython, some built-in functions defined in C provide no metadata about their arguments.

class inspect.Signature(*parameters=None*, ***, *return_annotation=Signature.empty*)

A Signature object represents the call signature of a function and its return annotation. For each parameter accepted by the function it stores a **`Parameter`** object in its **`parameters`** collection.

The optional *parameters* argument is a sequence of **`Parameter`** objects, which is validated to check that there are no parameters with duplicate names, and that the parameters are in the right order, i.e. positional-only first, then positional-or-keyword, and that parameters with defaults follow parameters without defaults.

The optional *return_annotation* argument, can be an arbitrary Python object, is the “return” annotation of the callable.

Signature objects are *immutable*. Use **`Signature.replace()`** to make a modified copy.

Changed in version 3.5: Signature objects are picklable and hashable.

empty

A special class-level marker to specify absence of a return annotation.

parameters

An ordered mapping of parameters' names to the corresponding **`Parameter`** objects. Parameters appear in strict definition order, including keyword-only parameters.

Changed in version 3.7: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

return_annotation

The "return" annotation for the callable. If the callable has no "return" annotation, this attribute is set to **`Signature.empty`**.

bind(**args*, ***kwargs*)

Create a mapping from positional and keyword arguments to parameters. Returns **`BoundArguments`** if `*args` and `**kwargs` match the signature, or raises a **`TypeError`**.

bind_partial(**args*, ***kwargs*)

Works the same way as **`Signature.bind()`**, but allows the omission of some required arguments (mimics **`functools.partial()`** behavior.) Returns **`BoundArguments`**, or raises a **`TypeError`** if the

passed arguments do not match the signature.

replace(**[, parameters][, return_annotation]*)

Create a new Signature instance based on the instance replace was invoked on. It is possible to pass different `parameters` and/or `return_annotation` to override the corresponding properties of the base signature. To remove return_annotation from the copied Signature, pass in **`Signature.empty`**.

```
>>> def test(a, b):
...     pass
>>> sig = signature(test)
>>> new_sig = sig.replace(return_annotation="ne
>>> str(new_sig)
"(a, b) -> 'new return anno'"
```

classmethod from_callable(*obj*, ***, *follow_wrapped=True*, *globalns=None*, *localns=None*)

Return a **`Signature`** (or its subclass) object for a given callable `obj`. Pass `follow_wrapped=False` to get a signature of `obj` without unwrapping its `__wrapped__` chain. `globalns` and `localns` will be used as the namespaces when resolving annotations.

This method simplifies subclassing of **`Signature`**:

```
class MySignature(Signature):
    pass
sig = MySignature.from_callable(min)
assert isinstance(sig, MySignature)
```

New in version 3.5.

New in version 3.10: `globalns` and `localns` parameters.

class inspect.Parameter(*name*, *kind*, ***, *default=Parameter.empty*, *annotation=Parameter.empty*)

Parameter objects are *immutable*. Instead of modifying a Parameter object, you can use `Parameter.replace()` to create a modified copy.

Changed in version 3.5: Parameter objects are picklable and hashable.

empty

A special class-level marker to specify absence of default values and annotations.

name

The name of the parameter as a string. The name must be a valid Python identifier.

CPython implementation detail: CPython generates implicit parameter names of the form `.0` on the code objects used to implement comprehensions and generator expressions.

Changed in version 3.6: These parameter names are exposed by this module as names like `implicit0`.

default

The default value for the parameter. If the parameter has no default value, this attribute is set to `Parameter.empty`.

annotation

The annotation for the parameter. If the parameter has no annotation, this attribute is set to `Parameter.empty`.

kind

Describes how argument values are bound to the parameter. Possible values (accessible via `Parameter`, like `Parameter.KEYWORD_ONLY`):

Name	Meaning

POSITIONAL_ONLY
: Value must be supplied as a positional argument. Positional only parameters are those which appear before a `/` entry (if present) in a Python function definition.

POSITIONAL_OR_KEYWORD
: Value may be supplied as either a keyword or positional argument (this is the standard binding behaviour for functions implemented in Python.)

VAR_POSITIONAL
: A tuple of positional arguments that aren't bound to any other parameter. This corresponds to a `*args` parameter in a Python function definition.

KEYWORD_ONLY
: Value must be supplied as a keyword argument. Keyword only parameters are those which appear after a `*` or `*args` entry in a Python function definition.

VAR_KEYWORD
: A dict of keyword arguments that aren't bound to any other parameter. This corresponds to a `**kwargs` parameter in a Python function definition.

Example: print all keyword-only arguments without default values:

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     if (param.kind == param.KEYWORD_ONLY ar
...                         param.default is par
...         print('Parameter:', param)
Parameter: c
```

kind.description

Describes a enum value of Parameter.kind.

New in version 3.8.

Example: print all descriptions of arguments:

```
>>> def foo(a, b, *, c, d=10):
```

```
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     print(param.kind.description)
positional or keyword
positional or keyword
keyword-only
keyword-only
```

replace(**[, name][, kind][, default][, annotation]*)

Create a new Parameter instance based on the instance replaced was invoked on. To override a **Parameter** attribute, pass the corresponding argument. To remove a default value or/and an annotation from a Parameter, pass **Parameter.empty**.

```
>>> from inspect import Parameter
>>> param = Parameter('foo', Parameter.KEYWORD_
>>> str(param)
'foo=42'

>>> str(param.replace()) # Will create a shallo
'foo=42'

>>> str(param.replace(default=Parameter.empty,
"foo:'spam'"
```

Changed in version 3.4: In Python 3.3 Parameter objects were allowed to have `name` set to `None` if their `kind` was set to `POSITIONAL_ONLY`. This is no longer permitted.

class inspect.BoundArguments

Result of a **Signature.bind()** or **Signature.bind_partial()** call. Holds the mapping of arguments to the function's parameters.

arguments

A mutable mapping of parameters' names to arguments' values. Contains only explicitly bound arguments. Changes in **arguments** will reflect in **args** and **kwargs**.

Should be used in conjunction with **Signature.parameters** for any argument processing purposes.

Note

Arguments for which **Signature.bind()** or **Signature.bind_partial()** relied on a default value are skipped. However, if needed, use **BoundArguments.apply_defaults()** to add them.

Changed in version 3.9: **arguments** is now of type **dict**. Formerly, it was of type **collections.OrderedDict**.

args

A tuple of positional arguments values. Dynamically computed from the **arguments** attribute.

kwargs

A dict of keyword arguments values. Dynamically computed from the **arguments** attribute.

signature

A reference to the parent **Signature** object.

apply_defaults()

Set default values for missing arguments.

For variable-positional arguments (`*args`) the default is an empty tuple.

For variable-keyword arguments (`**kwargs`) the

default is an empty dict.

```
>>> def foo(a, b='ham', *args): pass
>>> ba = inspect.signature(foo).bind('spam')
>>> ba.apply_defaults()
>>> ba.arguments
{'a': 'spam', 'b': 'ham', 'args': ()}
```

New in version 3.5.

The **args** and **kwargs** properties can be used to invoke functions:

```
def test(a, *, b):
    ...

sig = signature(test)
ba = sig.bind(10, b=20)
test(*ba.args, **ba.kwargs)
```

See also

PEP 362 **[https://peps.python.org/pep-0362/]** **- Function Signature Object.**
The detailed specification, implementation details and examples.

Classes and functions

inspect.getclasstree(*classes*, *unique*=*False*)

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the *unique* argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

inspect.getfullargspec(*func*)

Get the names and default values of a Python function's parameters. A named tuple is returned:

```
FullArgSpec(args, varargs, varkw, defaults,
kwonlyargs, kwonlydefaults, annotations)
```

args is a list of the positional parameter names. *varargs* is the name of the `*` parameter or `None` if arbitrary positional arguments are not accepted. *varkw* is the name of the `**` parameter or `None` if arbitrary keyword arguments are not accepted. *defaults* is an *n*-tuple of default argument values corresponding to the last *n* positional parameters, or `None` if there are no such defaults defined. *kwonlyargs* is a list of keyword-only parameter names in declaration order. *kwonlydefaults* is a dictionary mapping parameter names from *kwonlyargs* to the default values used if no argument is supplied. *annotations* is a dictionary mapping parameter names to annotations. The special key `"return"` is used to report the function return value annotation (if any).

Note that **`signature()`** and Signature Object provide the recommended API for callable introspection, and support additional behaviours (like positional-only arguments) that are sometimes encountered in extension module APIs. This function is retained primarily for use in code that needs to maintain compatibility with the Python 2 `inspect` module API.

Changed in version 3.4: This function is now based on **`signature()`**, but still ignores `__wrapped__` attributes and includes the already bound first parameter in the signature output for bound methods.

Changed in version 3.6: This method was previously documented as deprecated in favour of **`signature()`** in Python 3.5, but that decision has been reversed in order to restore a clearly supported standard interface for single-source Python 2/3 code migrating away from the legacy **`getargspec()`** API.

Changed in version 3.7: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

inspect.getargvalues(*frame*)

Get information about arguments passed into a particular frame. A named tuple `ArgInfo(args, varargs, keywords, locals)` is returned. *args* is a list of the argument names. *varargs* and *keywords* are the names of the `*` and `**` arguments or `None`. *locals* is the locals dictionary of the given frame.

Note

This function was inadvertently marked as deprecated in Python 3.5.

inspect.formatargvalues(*args*[, *varargs*, *varkw*, *locals*, *formatarg*, *formatvarargs*, *formatvarkw*, *formatvalue*])

Format a pretty argument spec from the four values returned by **`getargvalues()`**. The format* arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

Note

This function was inadvertently marked as deprecated in Python 3.5.

inspect.getmro(*cls*)

Return a tuple of class cls's base classes, including cls, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on cls's type. Unless a very peculiar user-defined metatype is in use, cls will be the first element of the tuple.

inspect.getcallargs(*func*, */*, **args*, ***kwds*)

Bind the *args* and *kwds* to the argument names of the Python function or method *func*, as if it was called with them. For bound methods, bind also the first argument (typically named `self`) to the associated instance. A dict is returned, mapping the argument names (including the names of the `*` and `**` arguments, if any) to their values from *args* and *kwds*. In case of invoking *func* incorrectly, i.e. whenever `func(*args, **kwds)` would raise an exception because of incompatible signature, an exception of the same type and the same or similar message is raised. For example:

```
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
>>> getcallargs(f, 1, 2, 3) == {'a': 1, 'named': {}
True
>>> getcallargs(f, a=2, x=4) == {'a': 2, 'named': {
True
>>> getcallargs(f)
Traceback (most recent call last):
...
TypeError: f() missing 1 required positional argume
```

New in version 3.2.

Deprecated since version 3.5: Use **`Signature.bind()`** and **`Signature.bind_partial()`** instead.

inspect.getclosurevars(*func*)

Get the mapping of external name references in a Python function or method *func* to their current values. A named tuple `ClosureVars(nonlocals, globals, builtins, unbound)` is returned. *nonlocals* maps referenced names to lexical closure variables, *globals* to the function's module globals and *builtins* to the builtins visible from the function body. *unbound* is the set of names referenced in the function that could not be resolved at all given the current module globals and builtins.

TypeError is raised if *func* is not a Python function or method.

New in version 3.3.

inspect.unwrap(*func*, *, *stop*=*None*)

Get the object wrapped by *func*. It follows the chain of **__wrapped__** attributes returning the last object in the chain.

stop is an optional callback accepting an object in the wrapper chain as its sole argument that allows the unwrapping to be terminated early if the callback returns a true value. If the callback never returns a true value, the last object in the chain is returned as usual. For example, **signature()** uses this to stop unwrapping if any object in the chain has a `__signature__` attribute defined.

ValueError is raised if a cycle is encountered.

New in version 3.4.

inspect.get_annotations(*obj*, *, *globals*=*None*, *locals*=*None*, *eval_str*=*False*)

Compute the annotations dict for an object.

`obj` may be a callable, class, or module. Passing in an object of any other type raises **TypeError**.

Returns a dict. `get_annotations()` returns a new dict every time it's called; calling it twice on the same object will return two different but equivalent dicts.

This function handles several details for you:

- If `eval_str` is true, values of type `str` will be un-stringized using **eval()**. This is intended for use with stringized annotations (`from __future__ import annotations`).
- If `obj` doesn't have an annotations dict, returns an

empty dict. (Functions and methods always have an annotations dict; classes, modules, and other types of callables may not.)

- Ignores inherited annotations on classes. If a class doesn't have its own annotations dict, returns an empty dict.
- All accesses to object members and dict values are done using `getattr()` and `dict.get()` for safety.
- Always, always, always returns a freshly created dict.

`eval_str` controls whether or not values of type `str` are replaced with the result of calling **`eval()`** on those values:

- If eval_str is true, **`eval()`** is called on values of type `str`. (Note that `get_annotations` doesn't catch exceptions; if **`eval()`** raises an exception, it will unwind the stack past the `get_annotations` call.)
- If eval_str is false (the default), values of type `str` are unchanged.

`globals` and `locals` are passed in to **`eval()`**; see the documentation for **`eval()`** for more information. If `globals` or `locals` is `None`, this function may replace that value with a context-specific default, contingent on `type(obj)`:

- If `obj` is a module, `globals` defaults to `obj.__dict__`.
- If `obj` is a class, `globals` defaults to `sys.modules[obj.__module__].__dict__` and `locals` defaults to the `obj` class namespace.
- If `obj` is a callable, `globals` defaults to `obj.__globals__`, although if `obj` is a wrapped function (using `functools.update_wrapper()`) it is first unwrapped.

Calling `get_annotations` is best practice for accessing the annotations dict of any object. See Annotations Best Practices for more information on annotations best practices.

New in version 3.10.

The interpreter stack

Some of the following functions return **`FrameInfo`** objects. For backwards compatibility these objects allow tuple-like operations on all attributes except `positions`. This behavior is considered deprecated and may be removed in the future.

class inspect.FrameInfo

frame

The frame object that the record corresponds to.

filename

The file name associated with the code being executed by the frame this record corresponds to.

lineno

The line number of the current line associated with the code being executed by the frame this record corresponds to.

function

The function name that is being executed by the frame this record corresponds to.

code_context

A list of lines of context from the source code that's being executed by the frame this record corresponds to.

index

The index of the current line being executed in the **`code_context`** list.

positions

A **`dis.Positions`** object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being

executed by the frame this record corresponds to.

Changed in version 3.5: Return a named tuple instead of a **`tuple`**.

Changed in version 3.11: **`FrameInfo`** is now a class instance (that is backwards compatible with the previous named tuple).

class inspect.Traceback

filename

The file name associated with the code being executed by the frame this traceback corresponds to.

lineno

The line number of the current line associated with the code being executed by the frame this traceback corresponds to.

function

The function name that is being executed by the frame this traceback corresponds to.

code_context

A list of lines of context from the source code that's being executed by the frame this traceback corresponds to.

index

The index of the current line being executed in the **`code_context`** list.

positions

A **`dis.Positions`** object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being executed by the frame this traceback corresponds to.

Changed in version 3.11: **`Traceback`** is now a class instance (that is backwards compatible with the previous named tuple).

Note

Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python's optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a **`finally`** clause. This is also important if the cycle detector was disabled when Python was compiled or using **`gc.disable()`**. For example:

```
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

If you want to keep the frame around (for example to print a traceback later), you can also break reference cycles by using the **`frame.clear()`** method.

The optional *context* argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

inspect.getframeinfo(*frame*, *context*=*1*)

Get information about a frame or traceback object. A

Traceback object is returned.

Changed in version 3.11: A **Traceback** object is returned instead of a named tuple.

inspect.getouterframes(*frame*, *context=1*)

Get a list of **FrameInfo** objects for a frame and all outer frames. These frames represent the calls that lead to the creation of *frame*. The first entry in the returned list represents *frame*; the last entry represents the outermost call on *frame*'s stack.

Changed in version 3.5: A list of named tuples `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

Changed in version 3.11: A list of **FrameInfo** objects is returned.

inspect.getinnerframes(*traceback*, *context=1*)

Get a list of **FrameInfo** objects for a traceback's frame and all inner frames. These frames represent calls made as a consequence of *frame*. The first entry in the list represents *traceback*; the last entry represents where the exception was raised.

Changed in version 3.5: A list of named tuples `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

Changed in version 3.11: A list of **FrameInfo** objects is returned.

inspect.currentframe()

Return the frame object for the caller's stack frame.

CPython implementation detail: This function relies on Python stack frame support in the interpreter, which isn't guaranteed to exist in all implementations of Python. If

running in an implementation without Python stack frame support this function returns `None`.

inspect.stack(*context=1*)

Return a list of **`FrameInfo`** objects for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

Changed in version 3.5: A list of named tuples `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

Changed in version 3.11: A list of **`FrameInfo`** objects is returned.

inspect.trace(*context=1*)

Return a list of **`FrameInfo`** objects for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.

Changed in version 3.5: A list of named tuples `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

Changed in version 3.11: A list of **`FrameInfo`** objects is returned.

Fetching attributes statically

Both **`getattr()`** and **`hasattr()`** can trigger code execution when fetching or checking for the existence of attributes. Descriptors, like properties, will be invoked and **`__getattr__()`** and **`__getattribute__()`** may be called.

For cases where you want passive introspection, like documentation tools, this can be inconvenient. **`getattr_static()`** has the same signature as **`getattr()`** but avoids executing code when it fetches

attributes.

inspect.getattr_static(*obj*, *attr*, *default*=*None*)

Retrieve attributes without triggering dynamic lookup via the descriptor protocol, **`__getattr__()`** or **`__getattribute__()`**.

Note: this function may not be able to retrieve all attributes that getattr can fetch (like dynamically created attributes) and may find attributes that getattr can't (like descriptors that raise AttributeError). It can also return descriptors objects instead of instance members.

If the instance **`__dict__`** is shadowed by another member (for example a property) then this function will be unable to find instance members.

New in version 3.2.

`getattr_static()` does not resolve descriptors, for example slot descriptors or getset descriptors on objects implemented in C. The descriptor object is returned instead of the underlying attribute.

You can handle these with code like the following. Note that for arbitrary getset descriptors invoking these may trigger code execution:

```
# example code for resolving the builtin descriptor type
class _foo:
    __slots__ = ['foo']

slot_descriptor = type(_foo.foo)
getset_descriptor = type(type(open(__file__)).name)
wrapper_descriptor = type(str.__dict__['__add__'])
descriptor_types = (slot_descriptor, getset_descriptor,

result = getattr_static(some_object, 'foo')
if type(result) in descriptor_types:
    try:
        result = result.__get__()
```

```
    except AttributeError:
        # descriptors can raise AttributeError to
        # indicate there is no underlying value
        # in which case the descriptor itself will
        # have to do
        pass
```

Current State of Generators and Coroutines

When implementing coroutine schedulers and for other advanced uses of generators, it is useful to determine whether a generator is currently executing, is waiting to start or resume or execution, or has already terminated. **`getgeneratorstate()`** allows the current state of a generator to be determined easily.

inspect.getgeneratorstate(*generator*)

Get current state of a generator-iterator.

Possible states are:

- GEN_CREATED: Waiting to start execution.
- GEN_RUNNING: Currently being executed by the interpreter.
- GEN_SUSPENDED: Currently suspended at a yield expression.
- GEN_CLOSED: Execution has completed.

New in version 3.2.

inspect.getcoroutinestate(*coroutine*)

Get current state of a coroutine object. The function is intended to be used with coroutine objects created by **`async def`** functions, but will accept any coroutine-like object that has `cr_running` and `cr_frame` attributes.

Possible states are:

- CORO_CREATED: Waiting to start execution.
- CORO_RUNNING: Currently being executed by

the interpreter.
- CORO_SUSPENDED: Currently suspended at an await expression.
- CORO_CLOSED: Execution has completed.

New in version 3.5.

The current internal state of the generator can also be queried. This is mostly useful for testing purposes, to ensure that internal state is being updated as expected:

inspect.getgeneratorlocals(*generator*)

Get the mapping of live local variables in *generator* to their current values. A dictionary is returned that maps from variable names to values. This is the equivalent of calling `locals()` in the body of the generator, and all the same caveats apply.

If *generator* is a generator with no currently associated frame, then an empty dictionary is returned. `TypeError` is raised if *generator* is not a Python generator object.

CPython implementation detail: This function relies on the generator exposing a Python stack frame for introspection, which isn't guaranteed to be the case in all implementations of Python. In such cases, this function will always return an empty dictionary.

New in version 3.3.

inspect.getcoroutinelocals(*coroutine*)

This function is analogous to `getgeneratorlocals()`, but works for coroutine objects created by `async def` functions.

New in version 3.5.

Code Objects Bit Flags

Python code objects have a `co_flags` attribute, which is a bitmap of the following flags:

inspect.CO_OPTIMIZED

The code object is optimized, using fast locals.

inspect.CO_NEWLOCALS

If set, a new dict will be created for the frame's `f_locals` when the code object is executed.

inspect.CO_VARARGS

The code object has a variable positional parameter (`*args`-like).

inspect.CO_VARKEYWORDS

The code object has a variable keyword parameter (`**kwargs`-like).

inspect.CO_NESTED

The flag is set when the code object is a nested function.

inspect.CO_GENERATOR

The flag is set when the code object is a generator function, i.e. a generator object is returned when the code object is executed.

inspect.CO_COROUTINE

The flag is set when the code object is a coroutine function. When the code object is executed it returns a coroutine object. See **PEP 492** [https://peps.python.org/pep-0492/] for more details.

New in version 3.5.

inspect.CO_ITERABLE_COROUTINE

The flag is used to transform generators into generator-based coroutines. Generator objects with this flag can be used in `await` expression, and can `yield from` coroutine objects.

See **PEP 492** [https://peps.python.org/pep-0492/] for more details.

New in version 3.5.

inspect.CO_ASYNC_GENERATOR

The flag is set when the code object is an asynchronous generator function. When the code object is executed it returns an asynchronous generator object. See **PEP 525** [https://peps.python.org/pep-0525/] for more details.

New in version 3.6.

Note

The flags are specific to CPython, and may not be defined in other Python implementations. Furthermore, the flags are an implementation detail, and can be removed or deprecated in future Python releases. It's recommended to use public APIs from the `inspect` module for any introspection needs.

Command Line Interface

The `inspect` module also provides a basic introspection capability from the command line.

By default, accepts the name of a module and prints the source of that module. A class or function within the module can be printed instead by appended a colon and the qualified name of the target object.

--details

Print information about the specified object rather than the source code

`site` — Site-specific configuration hook

Source code: Lib/site.py [https://github.com/python/cpython/tree/3.11/Lib/site.py]

This module is automatically imported during initialization. The automatic import can be suppressed using the interpreter's `-S` option.

Importing this module will append site-specific paths to the module search path and add a few builtins, unless `-S` was used. In that case, this module can be safely imported with no automatic modifications to the module search path or additions to the builtins. To explicitly trigger the usual site-specific additions, call the `site.main()` function.

Changed in version 3.3: Importing the module used to trigger paths manipulation even when using `-S`.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/pythonX.Y/site-packages` (on Unix and macOS). For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

Changed in version 3.5: Support for the "site-python" directory has been removed.

If a file named "pyvenv.cfg" exists one directory above sys.executable, sys.prefix and sys.exec_prefix are set to that directory and it is also checked for site-packages (sys.base_prefix

and sys.base_exec_prefix will always be the “real” prefixes of the Python installation). If “pyvenv.cfg” (a bootstrap configuration file) contains the key “include-system-site-packages” set to anything other than “true” (case-insensitive), the system-level prefixes will not be searched for site-packages; otherwise they will.

A path configuration file is a file whose name has the form *name*`.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, and no check is made that the item refers to a directory rather than a file. No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

Note

An executable line in a `.pth` file is run at every Python startup, regardless of whether a particular module is actually going to be used. Its impact should thus be kept to a minimum. The primary intended purpose of executable lines is to make the corresponding module(s) importable (load 3rd-party import hooks, adjust **`PATH`** etc). Any other initialization is supposed to be done upon a module’s actual import, if and when it happens. Limiting a code chunk to a single line is a deliberate measure to discourage putting anything more complex here.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python X.Y library is then installed in `/usr/local/lib/python`*`X.Y`*. Suppose this has a subdirectory `/usr/local/lib/python`*`X.Y`*`/site-packages` with three subsubdirectories, `foo`, `bar` and `spam`, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following:

```
# foo package configuration

foo
bar
bletch
```

and `bar.pth` contains:

```
# bar package configuration

bar
```

Then the following version-specific directories are added to `sys.path`, in this order:

```
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that `bletch` is omitted because it doesn't exist; the `bar` directory precedes the `foo` directory because `bar.pth` comes alphabetically before `foo.pth`; and `spam` is omitted because it is not mentioned in either path configuration file.

After these path manipulations, an attempt is made to import a module named **`sitecustomize`**, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the site-packages directory. If this import fails with an **`ImportError`** or its subclass exception, and the exception's **`name`** attribute equals to `'sitecustomize'`, it is silently ignored. If Python is started without output streams available, as with `pythonw.exe` on Windows (which is used by default to start IDLE), attempted output from **`sitecustomize`** is ignored. Any other exception causes a silent and perhaps mysterious failure of the process.

After this, an attempt is made to import a module named **`usercustomize`**, which can perform arbitrary user-specific customizations, if **`ENABLE_USER_SITE`** is true. This file is intended to be created in the user site-packages directory (see below), which is part of `sys.path` unless disabled by **`-s`**. If this import fails with an **`ImportError`** or its subclass exception, and the exception's **`name`** attribute equals to `'usercustomize'`, it is silently ignored.

Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of **`sitecustomize`** and

usercustomize is still attempted.

Readline configuration

On systems that support **readline**, this module will also import and configure the **rlcompleter** module, if Python is started in interactive mode and without the **-S** option. The default behavior is enable tab-completion and to use `~/.python_history` as the history save file. To disable it, delete (or override) the **sys.__interactivehook__** attribute in your **sitecustomize** or **usercustomize** module or your **PYTHONSTARTUP** file.

Changed in version 3.4: Activation of rlcompleter and history was made automatic.

Module contents

site.PREFIXES

A list of prefixes for site-packages directories.

site.ENABLE_USER_SITE

Flag showing the status of the user site-packages directory. `True` means that it is enabled and was added to `sys.path`. `False` means that it was disabled by user request (with **-s** or **PYTHONNOUSERSITE**). `None` means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

site.USER_SITE

Path to the user site-packages for the running Python. Can be `None` if **getusersitepackages()** hasn't been called yet. Default value is `~/.local/lib/pythonX.Y/site-packages` for UNIX and non-framework macOS builds, `~/Library/Python/X.Y/lib/python/site-packages` for macOS framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. This directory is a site directory, which means that `.pth` files in it will be processed.

site.USER_BASE

Path to the base directory for the user site-packages. Can be `None` if **`getuserbase()`** hasn't been called yet. Default value is `~/.local` for UNIX and macOS non-framework builds, `~/Library/Python/X.Y` for macOS framework builds, and `%APPDATA%\Python` for Windows. This value is used by Distutils to compute the installation directories for scripts, data files, Python modules, etc. for the user installation scheme. See also **`PYTHONUSERBASE`**.

site.main()

Adds all the standard site-specific directories to the module search path. This function is called automatically when this module is imported, unless the Python interpreter was started with the **`-S`** flag.

Changed in version 3.3: This function used to be called unconditionally.

site.addsitedir(*sitedir*, *known_paths*=*None*)

Add a directory to sys.path and process its `.pth` files. Typically used in **`sitecustomize`** or **`usercustomize`** (see above).

site.getsitepackages()

Return a list containing all global site-packages directories.

New in version 3.2.

site.getuserbase()

Return the path of the user base directory, **`USER_BASE`**. If it is not initialized yet, this function will also set it, respecting **`PYTHONUSERBASE`**.

New in version 3.2.

site.getusersitepackages()

Return the path of the user-specific site-packages directory, **USER_SITE**. If it is not initialized yet, this function will also set it, respecting **USER_BASE**. To determine if the user-specific site-packages was added to `sys.path` **ENABLE_USER_SITE** should be used.

New in version 3.2.

Command Line Interface

The **site** module also provides a way to get the user directories from the command line:

```
$ python3 -m site --user-site
/home/user/.local/lib/python3.3/site-packages
```

If it is called without arguments, it will print the contents of **sys.path** on the standard output, followed by the value of **USER_BASE** and whether the directory exists, then the same thing for **USER_SITE**, and finally the value of **ENABLE_USER_SITE**.

--user-base

Print the path to the user base directory.

--user-site

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by **os.pathsep**.

If any option is given, the script will exit with one of these values: `0` if the user site-packages directory is enabled, `1` if it was disabled by the user, `2` if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

Custom Python Interpreters

The modules described in this chapter allow writing interfaces similar to Python's interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the `code` module. (The `codeop` module is lower-level, used to support compiling a possibly incomplete chunk of Python code.)

The full list of modules described in this chapter is:

- `code` — Interpreter base classes
  - Interactive Interpreter Objects
  - Interactive Console Objects
- `codeop` — Compile Python code

code — Interpreter base classes

Source code: Lib/code.py [https://github.com/python/cpython/tree/3.11/Lib/code.py]

The `code` module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

class code.InteractiveInterpreter(*locals=None*)

This class deals with parsing and interpreter state (the user's namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional *locals* argument specifies the dictionary in which code will be executed; it defaults to a newly created dictionary with key `'__name__'` set to `'__console__'` and key `'__doc__'` set to `None`.

class code.InteractiveConsole(*locals=None*, *filename='<console>'*)

Closely emulate the behavior of the interactive Python interpreter. This class builds on **`InteractiveInterpreter`** and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering.

code.interact(*banner=None*, *readfunc=None*, *local=None*, *exitmsg=None*)

Convenience function to run a read-eval-print loop. This creates a new instance of **`InteractiveConsole`** and sets *readfunc* to be used as the **`InteractiveConsole.raw_input()`** method, if provided. If *local* is provided, it is passed to the **`InteractiveConsole`** constructor for use as the default namespace for the interpreter loop. The **`interact()`**

method of the instance is then run with *banner* and *exitmsg* passed as the banner and exit message to use, if provided. The console object is discarded after use.

Changed in version 3.6: Added *exitmsg* parameter.

code.compile_command(*source*, *filename*='<input>', *symbol*='single')

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

source is the source string; *filename* is the optional filename from which source was read, defaulting to `'<input>'`; and *symbol* is the optional grammar start symbol, which should be `'single'` (the default), `'eval'` or `'exec'`.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; `None` if the command is incomplete; raises **`SyntaxError`** if the command is complete and contains a syntax error, or raises **`OverflowError`** or **`ValueError`** if the command contains an invalid literal.

Interactive Interpreter Objects

InteractiveInterpreter.runsource(*source*, *filename*='<input>', *symbol*='single')

Compile and run some source in the interpreter. Arguments are the same as for **`compile_command()`**; the default for *filename* is `'<input>'`, and for *symbol* is `'single'`. One of several things can happen:

- The input is incorrect; **`compile_command()`** raised an exception (**`SyntaxError`** or **`OverflowError`**). A

syntax traceback will be printed by calling the **showsyntaxerror()** method. **runsource()** returns `False`.

- The input is incomplete, and more input is required; **compile_command()** returned `None`. **runsource()** returns `True`.
- The input is complete; **compile_command()** returned a code object. The code is executed by calling the **runcode()** (which also handles run-time exceptions, except for **SystemExit**). **runsource()** returns `False`.

The return value can be used to decide whether to use `sys.ps1` or `sys.ps2` to prompt the next line.

InteractiveInterpreter.runcode(*code*)

Execute a code object. When an exception occurs, **showtraceback()** is called to display a traceback. All exceptions are caught except **SystemExit**, which is allowed to propagate.

A note about **KeyboardInterrupt**: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

InteractiveInterpreter.showsyntaxerror(*filename=None*)

Display the syntax error that just occurred. This does not display a stack trace because there isn't one for syntax errors. If *filename* is given, it is stuffed into the exception instead of the default filename provided by Python's parser, because it always uses `'<string>'` when reading from a string. The output is written by the **write()** method.

InteractiveInterpreter.showtraceback()

Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the **write()** method.

Changed in version 3.5: The full chained traceback is displayed instead of just the primary traceback.

InteractiveInterpreter.write(*data*)

Write a string to the standard error stream (`sys.stderr`). Derived classes should override this to provide the appropriate output handling as needed.

Interactive Console Objects

The **`InteractiveConsole`** class is a subclass of **`InteractiveInterpreter`**, and so offers all the methods of the interpreter objects as well as the following additions.

InteractiveConsole.interact(*banner*=*None*, *exitmsg*=*None*)

Closely emulate the interactive Python console. The optional *banner* argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter – since it's so close!).

The optional *exitmsg* argument specifies an exit message printed when exiting. Pass the empty string to suppress the exit message. If *exitmsg* is not given or `None`, a default message is printed.

Changed in version 3.4: To suppress printing any banner, pass an empty string.

Changed in version 3.6: Print an exit message when exiting.

InteractiveConsole.push(*line*)

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's **`runsource()`** method is called with the concatenated contents of the buffer as source. If this indicates that the

command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as **`runsource()`**).

InteractiveConsole.resetbuffer()

Remove any unhandled source text from the input buffer.

InteractiveConsole.raw_input(*prompt*='')

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, **`EOFError`** is raised. The base implementation reads from `sys.stdin`; a subclass may replace this with a different implementation.

`codeop` — Compile Python code

Source code: Lib/codeop.py [https://github.com/python/cpython/tree/3.11/Lib/codeop.py]

The `codeop` module provides utilities upon which the Python read-eval-print loop can be emulated, as is done in the `code` module. As a result, you probably don't want to use the module directly; if you want to include such a loop in your program you probably want to use the `code` module instead.

There are two parts to this job:

1. Being able to tell if a line of input completes a Python statement: in short, telling whether to print '>>>' or '...' next.
2. Remembering which future statements the user has entered, so subsequent input can be compiled with these in effect.

The `codeop` module provides a way of doing each of these things, and a way of doing them both.

To do just the former:

codeop.compile_command(*source*, *filename*='<input>', *symbol*='single')

Tries to compile *source*, which should be a string of Python code and return a code object if *source* is valid Python code. In that case, the filename attribute of the code object will be *filename*, which defaults to `'<input>'`. Returns `None` if *source* is *not* valid Python code, but is a prefix of valid Python code.

If there is a problem with *source*, an exception will be raised.

SyntaxError is raised if there is invalid Python syntax, and **OverflowError** or **ValueError** if there is an invalid literal.

The *symbol* argument determines whether *source* is compiled as a statement (`'single'`, the default), as a sequence of statements (`'exec'`) or as an expression (`'eval'`). Any other value will cause **ValueError** to be raised.

Note

It is possible (but not likely) that the parser stops parsing with a successful outcome before reaching the end of the source; in this case, trailing symbols may be ignored instead of causing an error. For example, a backslash followed by two newlines may be followed by arbitrary garbage. This will be fixed once the API for the parser is better.

class codeop.Compile

Instances of this class have **__call__()** methods identical in signature to the built-in function **compile()**, but with the difference that if the instance compiles program text containing a **__future__** statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

class codeop.CommandCompiler

Instances of this class have **__call__()** methods identical in signature to **compile_command()**; the difference is that if the instance compiles program text containing a `__future__` statement, the instance 'remembers' and compiles all subsequent program texts with the statement in force.

Importing Modules

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

- **`zipimport`** — Import modules from Zip archives
  - zipimporter Objects
  - Examples
- **`pkgutil`** — Package extension utility
- **`modulefinder`** — Find modules used by a script
  - Example usage of **`ModuleFinder`**
- **`runpy`** — Locating and executing Python modules
- **`importlib`** — The implementation of **`import`**
  - Introduction
  - Functions
  - **`importlib.abc`** – Abstract base classes related to import
  - **`importlib.machinery`** – Importers and path hooks
  - **`importlib.util`** – Utility code for importers
  - Examples
    - Importing programmatically
    - Checking if a module can be imported
    - Importing a source file directly
    - Implementing lazy imports
    - Setting up an importer
    - Approximating **`importlib.import_module()`**

- **`importlib.resources`** – Resources
- Deprecated functions
- **`importlib.resources.abc`** – Abstract base classes for resources
- Using **`importlib.metadata`**
  - Overview
  - Functional API

    - Distribution versions
    - Distribution files
    - Distribution requirements
    - Mapping import to distribution packages
  - Distributions
  - Distribution Discovery
  - Extending the search algorithm
- The initialization of the **`sys.path`** module search path
  - Virtual environments
  - _pth files
  - Embedded Python

`zipimport` — Import modules from Zip archives

Source code: Lib/zipimport.py [https://github.com/python/cpython/tree/3.11/Lib/zipimport.py]

This module adds the ability to import Python modules (`*.py`, `*.pyc`) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in `import` mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but importers are only invoked for `.py` and `.pyc` files. ZIP import of dynamic modules (`.pyd`, `.so`) is disallowed. Note that if an archive only contains `.py` files, Python will not attempt to modify the archive by adding the corresponding `.pyc` file, meaning that if a ZIP archive doesn't contain `.pyc` files, importing may be rather slow.

Changed in version 3.8: Previously, ZIP archives with an archive comment were not supported.

PKZIP Application Note [https://pkware.cachefly.net/webdocs/casestudies/APPNOTE.TXT]
Documentation on the ZIP file format by Phil Katz, the

creator of the format and algorithms used.

PEP 273 [https://peps.python.org/pep-0273/] - Import Modules from Zip Archives
Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in **PEP 273** [https://peps.python.org/pep-0273/], but uses an implementation written by Just van Rossum that uses the import hooks described in **PEP 302** [https://peps.python.org/pep-0302/].

importlib - The implementation of the import machinery
Package providing the relevant protocols for all importers to implement.

This module defines an exception:

exception zipimport.ZipImportError
Exception raised by zipimporter objects. It's a subclass of **ImportError**, so it can be caught as **ImportError**, too.

zipimporter Objects

zipimporter is the class for importing ZIP files.

class zipimport.zipimporter(*archivepath*)
Create a new zipimporter instance. *archivepath* must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an *archivepath* of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).

ZipImportError is raised if *archivepath* doesn't point to a valid ZIP archive.

create_module(*spec*)
Implementation of **importlib.abc.Loader.create_module()** that returns **None** to explicitly request the default

semantics.

New in version 3.10.

exec_module(*module*)

Implementation of **importlib.abc.Loader.exec_module()**.

New in version 3.10.

find_loader(*fullname*, *path* = *None*)

An implementation of **importlib.abc.PathEntryFinder.find_loader()**.

Deprecated since version 3.10: Use **find_spec()** instead.

find_module(*fullname*, *path* = *None*)

Search for a module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. It returns the zipimporter instance itself if the module was found, or **None** if it wasn't. The optional *path* argument is ignored—it's there for compatibility with the importer protocol.

Deprecated since version 3.10: Use **find_spec()** instead.

find_spec(*fullname*, *target* = *None*)

An implementation of **importlib.abc.PathEntryFinder.find_spec()**.

New in version 3.10.

get_code(*fullname*)

Return the code object for the specified module. Raise **ZipImportError** if the module couldn't be imported.

get_data(*pathname*)

Return the data associated with *pathname*. Raise **OSError** if the file wasn't found.

Changed in version 3.3: **IOError** used to be raised instead of **OSError**.

get_filename(*fullname*)

Return the value `__file__` would be set to if the specified module was imported. Raise **ZipImportError** if the module couldn't be imported.

New in version 3.1.

get_source(*fullname*)

Return the source code for the specified module. Raise **ZipImportError** if the module couldn't be found, return **None** if the archive does contain the module, but has no source for it.

is_package(*fullname*)

Return `True` if the module specified by *fullname* is a package. Raise **ZipImportError** if the module couldn't be found.

load_module(*fullname*)

Load the module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. Returns the imported module on success, raises **ZipImportError** on failure.

Deprecated since version 3.10: Use **exec_module()** instead.

invalidate_caches()

Clear out the internal cache of information about files found within the ZIP archive.

New in version 3.10.

archive

The file name of the importer's associated ZIP file, without a possible subpath.

prefix

The subpath within the ZIP file where modules are searched. This is the empty string for zipimporter objects which point to the root of the ZIP file.

The **archive** and **prefix** attributes, when combined with a slash, equal the original *archivepath* argument given to the **zipimporter** constructor.

Examples

Here is an example that imports a module from a ZIP archive - note that the **zipimport** module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
  Length     Date   Time    Name
 --------    ----   ----    ----
     8467  11-26-02 22:30   jwzthreading.py
 --------                   -------
     8467                   1 file
$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip')  # Add .zip file t
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```

`pkgutil` — Package extension utility

Source code: Lib/pkgutil.py [https://github.com/python/cpython/tree/3.11/Lib/pkgutil.py]

This module provides utilities for the import system, in particular package support.

class pkgutil.ModuleInfo(*module_finder*, *name*, *ispkg*)

A namedtuple that holds a brief summary of a module's info.

New in version 3.6.

pkgutil.extend_path(*path*, *name*)

Extend the search path for the modules which comprise a package. Intended use is to place the following code in a package's `__init__.py`:

```
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

This will add to the package's `__path__` all subdirectories of directories on `sys.path` named after the package. This is useful if one wants to distribute different parts of a single logical package as multiple directories.

It also looks for `*.pkg` files beginning where `*` matches the *name* argument. This feature is similar to `*.pth` files (see the `site` module for more information), except that it doesn't special-case lines starting with `import`. A `*.pkg` file is trusted at face value: apart from checking for duplicates, all entries found in a `*.pkg` file are added to the path, regardless of whether they exist on the filesystem. (This is a

feature.)

If the input path is not a list (as is the case for frozen packages) it is returned unchanged. The input path is not modified; an extended copy is returned. Items are only appended to the copy at the end.

It is assumed that **sys.path** is a sequence. Items of **sys.path** that are not strings referring to existing directories are ignored. Unicode items on **sys.path** that cause errors when used as filenames may cause this function to raise an exception (in line with **os.path.isdir()** behavior).

class pkgutil.ImpImporter(*dirname=None*)

PEP 302 [https://peps.python.org/pep-0302/] Finder that wraps Python's "classic" import algorithm.

If *dirname* is a string, a **PEP 302** [https://peps.python.org/pep-0302/] finder is created that searches that directory. If *dirname* is `None`, a **PEP 302** [https://peps.python.org/pep-0302/] finder is created that searches the current **sys.path**, plus any modules that are frozen or built-in.

Note that **ImpImporter** does not currently support being used by placement on **sys.meta_path**.

Deprecated since version 3.3: This emulation is no longer needed, as the standard import mechanism is now fully **PEP 302** [https://peps.python.org/pep-0302/] compliant and available in **importlib**.

class pkgutil.ImpLoader(*fullname*, *file*, *filename*, *etc*)

Loader that wraps Python's "classic" import algorithm.

Deprecated since version 3.3: This emulation is no longer needed, as the standard import mechanism is now fully **PEP 302** [https://peps.python.org/pep-0302/] compliant and available in **importlib**.

pkgutil.find_loader(*fullname*)

Retrieve a module loader for the given *fullname*.

This is a backwards compatibility wrapper around **importlib.util.find_spec()** that converts most failures to **ImportError** and only returns the loader rather than the full **ModuleSpec**.

Changed in version 3.3: Updated to be based directly on **importlib** rather than relying on the package internal **PEP 302** [https://peps.python.org/pep-0302/] import emulation.

Changed in version 3.4: Updated to be based on **PEP 451** [https://peps.python.org/pep-0451/]

pkgutil.get_importer(*path_item*)

Retrieve a finder for the given *path_item*.

The returned finder is cached in **sys.path_importer_cache** if it was newly created by a path hook.

The cache (or part of it) can be cleared manually if a rescan of **sys.path_hooks** is necessary.

Changed in version 3.3: Updated to be based directly on **importlib** rather than relying on the package internal **PEP 302** [https://peps.python.org/pep-0302/] import emulation.

pkgutil.get_loader(*module_or_name*)

Get a loader object for *module_or_name*.

If the module or package is accessible via the normal import mechanism, a wrapper around the relevant part of that machinery is returned. Returns `None` if the module cannot be found or imported. If the named module is not already imported, its containing package (if any) is imported, in order to establish the package `__path__`.

Changed in version 3.3: Updated to be based directly on

importlib rather than relying on the package internal **PEP 302** [https://peps.python.org/pep-0302/] import emulation.

Changed in version 3.4: Updated to be based on **PEP 451** [https://peps.python.org/pep-0451/]

pkgutil.iter_importers(*fullname* = '')

Yield finder objects for the given module name.

If fullname contains a `'.'`, the finders will be for the package containing fullname, otherwise they will be all registered top level finders (i.e. those on both **sys.meta_path** and **sys.path_hooks**).

If the named module is in a package, that package is imported as a side effect of invoking this function.

If no module name is specified, all top level finders are produced.

Changed in version 3.3: Updated to be based directly on **importlib** rather than relying on the package internal **PEP 302** [https://peps.python.org/pep-0302/] import emulation.

pkgutil.iter_modules(*path* = *None*, *prefix* = '')

Yields **ModuleInfo** for all submodules on *path*, or, if *path* is `None`, all top-level modules on **sys.path**.

path should be either `None` or a list of paths to look for modules in.

prefix is a string to output on the front of every module name on output.

Note

Only works for a finder which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for **importlib.machinery.FileFinder** and

zipimport.zipimporter.

Changed in version 3.3: Updated to be based directly on **importlib** rather than relying on the package internal **PEP 302** [https://peps.python.org/pep-0302/] import emulation.

pkgutil.walk_packages(*path=None*, *prefix=''*, *onerror=None*)

Yields **ModuleInfo** for all modules recursively on *path*, or, if *path* is `None`, all accessible modules.

path should be either `None` or a list of paths to look for modules in.

prefix is a string to output on the front of every module name on output.

Note that this function must import all *packages* (*not* all modules!) on the given *path*, in order to access the `__path__` attribute to find submodules.

onerror is a function which gets called with one argument (the name of the package which was being imported) if any exception occurs while trying to import a package. If no *onerror* function is supplied, **ImportError**s are caught and ignored, while all other exceptions are propagated, terminating the search.

Examples:

```
# list all modules python can access
walk_packages()

# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ + '.
```

Note

Only works for a finder which defines an `iter_modules()` method. This interface is non-standard, so the module also provides implementations for

importlib.machinery.FileFinder and **zipimport.zipimporter**.

Changed in version 3.3: Updated to be based directly on **importlib** rather than relying on the package internal **PEP 302** [https://peps.python.org/pep-0302/] import emulation.

pkgutil.get_data(*package*, *resource*)

Get a resource from a package.

This is a wrapper for the loader **get_data** API. The *package* argument should be the name of a package, in standard module format (`foo.bar`). The *resource* argument should be in the form of a relative filename, using `/` as the path separator. The parent directory name `..` is not allowed, and nor is a rooted name (starting with a `/`).

The function returns a binary string that is the contents of the specified resource.

For packages located in the filesystem, which have already been imported, this is the rough equivalent of:

```
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()
```

If the package cannot be located or loaded, or it uses a loader which does not support **get_data**, then `None` is returned. In particular, the loader for namespace packages does not support **get_data**.

pkgutil.resolve_name(*name*)

Resolve a name to an object.

This functionality is used in numerous places in the standard library (see bpo-12915 [https://bugs.python.org/issue?@action=redirect&bpo=12915]) - and equivalent functionality is also in widely used third-party packages such as setuptools, Django and Pyramid.

It is expected that *name* will be a string in one of the following formats, where W is shorthand for a valid Python identifier and dot stands for a literal period in these pseudo-regexes:

- `W(.W)*`
- `W(.W)*:(W(.W)*)?`

The first form is intended for backward compatibility only. It assumes that some part of the dotted name is a package, and the rest is an object somewhere within that package, possibly nested inside other objects. Because the place where the package stops and the object hierarchy starts can't be inferred by inspection, repeated attempts to import must be done with this form.

In the second form, the caller makes the division point clear through the provision of a single colon: the dotted name to the left of the colon is a package to be imported, and the dotted name to the right is the object hierarchy within that package. Only one import is needed in this form. If it ends with the colon, then a module object is returned.

The function will return an object (which might be a module), or raise one of the following exceptions:

`ValueError` – if *name* isn't in a recognised format.

`ImportError` – if an import failed when it shouldn't have.

`AttributeError` – If a failure occurred when traversing the object hierarchy within the imported package to get to the desired object.

New in version 3.9.

`modulefinder` — Find modules used by a script

Source code: Lib/modulefinder.py [https://github.com/python/cpython/tree/3.11/Lib/modulefinder.py]

This module provides a `ModuleFinder` class that can be used to determine the set of modules imported by a script. `modulefinder.py` can also be run as a script, giving the filename of a Python script as its argument, after which a report of the imported modules will be printed.

modulefinder.AddPackagePath(*pkg_name*, *path*)

Record that the package named *pkg_name* can be found in the specified *path*.

modulefinder.ReplacePackage(*oldname*, *newname*)

Allows specifying that the module named *oldname* is in fact the package named *newname*.

class modulefinder.ModuleFinder(*path=None*, *debug=0*, *excludes=[]*, *replace_paths=[]*)

This class provides `run_script()` and `report()` methods to determine the set of modules imported by a script. *path* can be a list of directories to search for modules; if not specified, `sys.path` is used. *debug* sets the debugging level; higher values make the class print debugging messages about what it's doing. *excludes* is a list of module names to exclude from the analysis. *replace_paths* is a list of `(oldpath, newpath)` tuples that will be replaced in module paths.

report()

Print a report to standard output that lists the modules imported by the script and their paths, as well as modules that are missing or seem to be missing.

run_script(*pathname*)

Analyze the contents of the *pathname* file, which must contain Python code.

modules

A dictionary mapping module names to modules. See Example usage of ModuleFinder.

Example usage of `ModuleFinder`

The script that is going to get analyzed later on (bacon.py):

```
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

The script that will output the report of bacon.py:

```
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print('Loaded modules:')
for name, mod in finder.modules.items():
    print('%s: ' % name, end='')
```

```
    print(',',.join(list(mod.globalnames.keys())[:3]))

print('-'*50)
print('Modules not imported:')
print('\n'.join(finder.badmodules.keys()))
```

Sample output (may vary depending on the architecture):

```
Loaded modules:
_types:
copyreg:  _inverted_registry,_slotnames,__all__
re._compiler:  isstring,_sre,_optimize_unicode
_sre:
re._constants:  REPEAT_ONE,makedict,AT_END_LINE
sys:
re:  __module__,finditer,_expand
itertools:
__main__:  re,itertools,baconhameggs
re._parser:  _PATTERNENDERS,SRE_FLAG_UNICODE
array:
types:  __module__,IntType,TypeType
--------------------------------------------------
Modules not imported:
guido.python.ham
baconhameggs
```

`runpy` — Locating and executing Python modules

Source code: Lib/runpy.py [https://github.com/python/cpython/tree/3.11/Lib/runpy.py]

The `runpy` module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

Note that this is *not* a sandbox module - all code is executed in the current process, and any side effects (such as cached imports of other modules) will remain in place after the functions have returned.

Furthermore, any functions and classes defined by the executed code are not guaranteed to work correctly after a `runpy` function has returned. If that limitation is not acceptable for a given use case, `importlib` is likely to be a more suitable choice than this module.

The `runpy` module provides two functions:

runpy.run_module(*mod_name*, *init_globals*=*None*, *run_name*=*None*, *alter_sys*=*False*)

Execute the code of the specified module and return the resulting module globals dictionary. The module's code is first located using the standard import mechanism (refer to **PEP 302** [https://peps.python.org/pep-0302/] for details) and then executed in a fresh module namespace.

The *mod_name* argument should be an absolute module name. If the module name refers to a package rather than a normal

module, then that package is imported and the `__main__` submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument *init_globals* may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by **`run_module()`**.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to *run_name* if this optional argument is not **`None`**, to `mod_name + '.__main__'` if the named module is a package and to the *mod_name* argument otherwise.

`__spec__` will be set appropriately for the *actually* imported module (that is, `__spec__.name` will always be *mod_name* or `mod_name + '.__main__'`, never *run_name*).

`__file__`, `__cached__`, `__loader__` and `__package__` are set as normal based on the module spec.

If the argument *alter_sys* is supplied and evaluates to **`True`**, then `sys.argv[0]` is updated with the value of `__file__` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. Both `sys.argv[0]` and `sys.modules[__name__]` are restored to their original values before the function returns.

Note that this manipulation of **`sys`** is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the **`sys`** module be left alone when invoking this function from threaded code.

See also

The **-m** option offering equivalent functionality from the command line.

Changed in version 3.1: Added ability to execute packages by looking for a `__main__` submodule.

Changed in version 3.2: Added `__cached__` global variable (see **PEP 3147** [https://peps.python.org/pep-3147/]).

Changed in version 3.4: Updated to take advantage of the module spec feature added by **PEP 451** [https://peps.python.org/pep-0451/]. This allows `__cached__` to be set correctly for modules run this way, as well as ensuring the real module name is always accessible as `__spec__.name`.

runpy.run_path(*path_name*, *init_globals*=*None*, *run_name*=*None*)

Execute the code at the named filesystem location and return the resulting module globals dictionary. As with a script name supplied to the CPython command line, the supplied path may refer to a Python source file, a compiled bytecode file or a valid sys.path entry containing a `__main__` module (e.g. a zipfile containing a top-level `__main__.py` file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid sys.path entry (typically a zipfile or directory), the entry is first added to the beginning of `sys.path`. The function then looks for and executes a **__main__** module using the updated path. Note that there is no special protection against invoking an existing **__main__** entry located elsewhere on `sys.path` if there is no such module at the specified location.

The optional dictionary argument *init_globals* may be used to pre-populate the module's globals dictionary before the code is executed. The supplied dictionary will not be modified. If any of the special global variables below are defined in the supplied dictionary, those definitions are overridden by **run_path()**.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail).

`__name__` is set to *run_name* if this optional argument is not **`None`** and to `'<run_path>'` otherwise.

If the supplied path directly references a script file (whether as source or as precompiled byte code), then `__file__` will be set to the supplied path, and `__spec__`, `__cached__`, `__loader__` and `__package__` will all be set to **`None`**.

If the supplied path is a reference to a valid sys.path entry, then `__spec__` will be set appropriately for the imported `__main__` module (that is, `__spec__.name` will always be `__main__`). `__file__`, `__cached__`, `__loader__` and `__package__` will be set as normal based on the module spec.

A number of alterations are also made to the **`sys`** module. Firstly, `sys.path` may be altered as described above. `sys.argv[0]` is updated with the value of `path_name` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. All modifications to items in **`sys`** are reverted before the function returns.

Note that, unlike **`run_module()`**, the alterations made to **`sys`** are not optional in this function as these adjustments are essential to allowing the execution of sys.path entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

See also

Interface options for equivalent functionality on the command line (`python path/to/script`).

New in version 3.2.

Changed in version 3.4: Updated to take advantage of the module spec feature added by **PEP 451** [https://peps.python.org/pep-0451/]. This allows `__cached__` to be set correctly in the case where `__main__` is imported from a valid sys.path entry rather than being executed directly.

Command line and environment - CPython command line details

The **`importlib.import_module()`** function

`importlib` — The implementation of `import`

New in version 3.1.

Source code: Lib/importlib/_init_.py [https://github.com/python/cpython/tree/3.11/Lib/importlib/_init_.py]

Introduction

The purpose of the **`importlib`** package is three-fold.

One is to provide the implementation of the **`import`** statement (and thus, by extension, the **`__import__()`** function) in Python source code. This provides an implementation of **`import`** which is portable to any Python interpreter. This also provides an implementation which is easier to comprehend than one implemented in a programming language other than Python.

Two, the components to implement **`import`** are exposed in this package, making it easier for users to create their own custom objects (known generically as an importer) to participate in the import process.

Three, the package contains modules exposing additional functionality for managing aspects of Python packages:

- **`importlib.metadata`** presents access to metadata from third-party distributions.
- **`importlib.resources`** provides routines for accessing non-code "resources" from Python packages.

Functions

importlib._import_(*name*, *globals*=*None*, *locals*=*None*, *fromlist*=*()*, *level*=*0*)

An implementation of the built-in **`__import__()`** function.

Note

Programmatic importing of modules should use **`import_module()`** instead of this function.

importlib.import_module(*name*, *package*=*None*)

Import a module. The *name* argument specifies what module to import in absolute or relative terms (e.g. either `pkg.mod` or `..mod`). If the name is specified in relative terms, then the *package* argument must be set to the name of the package which is to act as the anchor for resolving the package name (e.g. `import_module('..mod', 'pkg.subpkg')` will import `pkg.mod`).

The **`import_module()`** function acts as a simplifying wrapper around **`importlib.__import__()`**. This means all semantics of the function are derived from **`importlib.__import__()`**. The most important difference between these two functions is that **`import_module()`** returns the specified package or module (e.g. `pkg.mod`), while **`__import__()`** returns the top-level package or module (e.g. `pkg`).

If you are dynamically importing a module that was created since the interpreter began execution (e.g., created a Python source file), you may need to call **`invalidate_caches()`** in order for the new module to be noticed by the import system.

Changed in version 3.3: Parent packages are automatically imported.

importlib.find_loader(*name*, *path*=*None*)

Find the loader for a module, optionally within the specified *path*. If the module is in **`sys.modules`**, then `sys.modules[name].__loader__` is returned (unless the loader would be `None` or is not set, in which case **`ValueError`** is raised). Otherwise a search using **`sys.meta_path`** is done. `None` is returned if no loader is found.

A dotted name does not have its parents implicitly imported as that requires loading them and that may not be desired. To properly import a submodule you will need to import all parent packages of the submodule and use the correct argument to *path*.

New in version 3.3.

Changed in version 3.4: If `__loader__` is not set, raise **`ValueError`**, just like when the attribute is set to `None`.

Deprecated since version 3.4: Use **`importlib.util.find_spec()`** instead.

importlib.invalidate_caches()

Invalidate the internal caches of finders stored at **`sys.meta_path`**. If a finder implements `invalidate_caches()` then it will be called to perform the invalidation. This function should be called if any modules are created/installed while your program is running to guarantee all finders will notice the new module's existence.

New in version 3.3.

Changed in version 3.10: Namespace packages created/installed in a different `sys.path` location after the same namespace was already imported are noticed.

importlib.reload(*module*)

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (which can be different if re-importing causes a different object to be placed in `sys.modules`).

When `reload()` is executed:

- Python module's code is recompiled and the module-level code re-executed, defining a new set of objects which are bound to names in the module's dictionary by reusing the loader which originally loaded the module. The `init` function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition

remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects — with a **try** statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading **sys**, **__main__**, **builtins** and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using **from** … **import** …, calling **reload()** for the other module does not redefine the objects imported from it — one way around this is to re-execute the **from** statement, another is to use **import** and qualified names (*module.name*) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances — they continue to use the old class definition. The same is true for derived classes.

New in version 3.4.

Changed in version 3.7: **ModuleNotFoundError** is raised when the module being reloaded lacks a **ModuleSpec**.

importlib.abc – Abstract base classes related to import

Source code: Lib/importlib/abc.py [https://github.com/python/cpython/tree/3.11/Lib/importlib/abc.py]

The **importlib.abc** module contains all of the core abstract base classes used by **import**. Some subclasses of the core abstract base classes are also provided to help in implementing the core ABCs.

ABC hierarchy:

```
object
 +-- Finder (deprecated)
 +-- MetaPathFinder
 +-- PathEntryFinder
 +-- Loader
      +-- ResourceLoader --------+
      +-- InspectLoader          |
           +-- ExecutionLoader --+
                                 +-- FileLoader
                                 +-- SourceLoader
```

class importlib.abc.Finder

An abstract base class representing a finder.

Deprecated since version 3.3: Use **MetaPathFinder** or **PathEntryFinder** instead.

abstractmethod find_module(*fullname*, *path=None*)

An abstract method for finding a loader for the specified module. Originally specified in **PEP 302** [https://peps.python.org/pep-0302/], this method was meant for use in **sys.meta_path** and in the path-based import subsystem.

Changed in version 3.4: Returns `None` when called instead of raising **NotImplementedError**.

Deprecated since version 3.10: Implement **MetaPathFinder.find_spec()** or **PathEntryFinder.find_spec()** instead.

class importlib.abc.MetaPathFinder

An abstract base class representing a meta path finder.

New in version 3.3.

Changed in version 3.10: No longer a subclass of **Finder**.

find_spec(*fullname*, *path*, *target=None*)

An abstract method for finding a spec for the specified module. If this is a top-level import, *path* will be `None`. Otherwise, this is a search for a subpackage or module and *path* will be the value of **__path__** from the parent package. If a spec cannot be found, `None` is returned. When passed in, `target` is a module object that the finder may use to make a more educated guess about what spec to return. **importlib.util.spec_from_loader()** may be useful for implementing concrete `MetaPathFinders`.

New in version 3.4.

find_module(*fullname*, *path*)

A legacy method for finding a loader for the specified module. If this is a top-level import, *path* will be `None`. Otherwise, this is a search for a subpackage or module and *path* will be the value of **__path__** from the parent package. If a loader cannot be found, `None` is returned.

If **find_spec()** is defined, backwards-compatible functionality is provided.

Changed in version 3.4: Returns `None` when called instead of raising **NotImplementedError**. Can use **find_spec()** to provide functionality.

Deprecated since version 3.4: Use **find_spec()** instead.

invalidate_caches()

An optional method which, when called, should invalidate any internal cache used by the finder. Used

by **importlib.invalidate_caches()** when invalidating the caches of all finders on **sys.meta_path**.

Changed in version 3.4: Returns `None` when called instead of `NotImplemented`.

class importlib.abc.PathEntryFinder

An abstract base class representing a path entry finder. Though it bears some similarities to **MetaPathFinder**, `PathEntryFinder` is meant for use only within the path-based import subsystem provided by **importlib.machinery.PathFinder**.

New in version 3.3.

Changed in version 3.10: No longer a subclass of **Finder**.

find_spec(*fullname*, *target=None*)

An abstract method for finding a spec for the specified module. The finder will search for the module only within the path entry to which it is assigned. If a spec cannot be found, `None` is returned. When passed in, `target` is a module object that the finder may use to make a more educated guess about what spec to return. **importlib.util.spec_from_loader()** may be useful for implementing concrete `PathEntryFinders`.

New in version 3.4.

find_loader(*fullname*)

A legacy method for finding a loader for the specified module. Returns a 2-tuple of `(loader, portion)` where `portion` is a sequence of file system locations contributing to part of a namespace package. The loader may be `None` while specifying `portion` to signify the contribution of the file system locations to a namespace package. An empty list can be used for

`portion` to signify the loader is not part of a namespace package. If `loader` is `None` and `portion` is the empty list then no loader or location for a namespace package were found (i.e. failure to find anything for the module).

If **`find_spec()`** is defined then backwards-compatible functionality is provided.

Changed in version 3.4: Returns `(None, [])` instead of raising **`NotImplementedError`**. Uses **`find_spec()`** when available to provide functionality.

Deprecated since version 3.4: Use **`find_spec()`** instead.

find_module(*fullname*)

A concrete implementation of **`Finder.find_module()`** which is equivalent to `self.find_loader(fullname)[0]`.

Deprecated since version 3.4: Use **`find_spec()`** instead.

invalidate_caches()

An optional method which, when called, should invalidate any internal cache used by the finder. Used by **`importlib.machinery.PathFinder.invalidate_cache`** when invalidating the caches of all cached finders.

class importlib.abc.Loader

An abstract base class for a loader. See **PEP 302** [https://peps.python.org/pep-0302/] for the exact definition for a loader.

Loaders that wish to support resource reading should implement a **`get_resource_reader()`** method as specified by **`importlib.resources.abc.ResourceReader`**.

Changed in version 3.7: Introduced the optional **`get_resource_reader()`** method.

create_module(*spec*)

A method that returns the module object to use when importing a module. This method may return `None`, indicating that default module creation semantics should take place.

New in version 3.4.

Changed in version 3.6: This method is no longer optional when **`exec_module()`** is defined.

exec_module(*module*)

An abstract method that executes the module in its own namespace when a module is imported or reloaded. The module should already be initialized when **`exec_module()`** is called. When this method exists, **`create_module()`** must be defined.

New in version 3.4.

Changed in version 3.6: **`create_module()`** must also be defined.

load_module(*fullname*)

A legacy method for loading a module. If the module cannot be loaded, **`ImportError`** is raised, otherwise the loaded module is returned.

If the requested module already exists in **`sys.modules`**, that module should be used and reloaded. Otherwise the loader should create a new module and insert it into **`sys.modules`** before any loading begins, to prevent recursion from the import. If the loader inserted a module and the load fails, it must be removed by the loader from **`sys.modules`**; modules already in **`sys.modules`** before the loader

began execution should be left alone (see **importlib.util.module_for_loader()**).

The loader should set several attributes on the module (note that some of these attributes can change when a module is reloaded):

- **__name__**
  The module's fully qualified name. It is `'__main__'` for an executed module.

- **__file__**
  The location the loader used to load the module. For example, for modules loaded from a .py file this is the filename. It is not set on all modules (e.g. built-in modules).

- **__cached__**
  The filename of a compiled version of the module's code. It is not set on all modules (e.g. built-in modules).

- **__path__**
  The list of locations where the package's submodules will be found. Most of the time this is a single directory. The import system passes this attribute to `__import__()` and to finders in the same way as **sys.path** but just for the package. It is not set on non-package modules so it can be used as an indicator that the module is a package.

- **__package__**
  The fully qualified name of the package the module is in (or the empty string for a top-level module). If the module is a package then this is the same as **__name__**.

- **__loader__**

The loader used to load the module.

When **exec_module()** is available then backwards-compatible functionality is provided.

Changed in version 3.4: Raise **ImportError** when called instead of **NotImplementedError**. Functionality provided when **exec_module()** is available.

Deprecated since version 3.4: The recommended API for loading a module is **exec_module()** (and **create_module()**). Loaders should implement it instead of **load_module()**. The import machinery takes care of all the other responsibilities of **load_module()** when **exec_module()** is implemented.

module_repr(*module*)

A legacy method which when implemented calculates and returns the given module's representation, as a string. The module type's default **__repr__()** will use the result of this method as appropriate.

New in version 3.3.

Changed in version 3.4: Made optional instead of an abstractmethod.

Deprecated since version 3.4: The import machinery now takes care of this automatically.

class importlib.abc.ResourceLoader

An abstract base class for a loader which implements the optional **PEP 302** [https://peps.python.org/pep-0302/] protocol for loading arbitrary resources from the storage back-end.

Deprecated since version 3.7: This ABC is deprecated in favour of supporting resource loading through **importlib.resources.abc.ResourceReader**.

abstractmethod get_data(*path*)

An abstract method to return the bytes for the data located at *path*. Loaders that have a file-like storage back-end that allows storing arbitrary data can implement this abstract method to give direct access to the data stored. **OSError** is to be raised if the *path* cannot be found. The *path* is expected to be constructed using a module's **__file__** attribute or an item from a package's **__path__**.

Changed in version 3.4: Raises **OSError** instead of **NotImplementedError**.

class importlib.abc.InspectLoader

An abstract base class for a loader which implements the optional **PEP 302** [https://peps.python.org/pep-0302/] protocol for loaders that inspect modules.

get_code(*fullname*)

Return the code object for a module, or `None` if the module does not have a code object (as would be the case, for example, for a built-in module). Raise an **ImportError** if loader cannot find the requested module.

Note

While the method has a default implementation, it is suggested that it be overridden if possible for performance.

Changed in version 3.4: No longer abstract and a concrete implementation is provided.

abstractmethod get_source(*fullname*)

An abstract method to return the source of a module. It is returned as a text string using universal newlines, translating all recognized line separators into `'\n'`

characters. Returns `None` if no source is available (e.g. a built-in module). Raises **`ImportError`** if the loader cannot find the module specified.

Changed in version 3.4: Raises **`ImportError`** instead of **`NotImplementedError`**.

is_package(*fullname*)

An optional method to return a true value if the module is a package, a false value otherwise. **`ImportError`** is raised if the loader cannot find the module.

Changed in version 3.4: Raises **`ImportError`** instead of **`NotImplementedError`**.

static source_to_code(*data*, *path*='<*string*>')

Create a code object from Python source.

The *data* argument can be whatever the **`compile()`** function supports (i.e. string or bytes). The *path* argument should be the "path" to where the source code originated from, which can be an abstract concept (e.g. location in a zip file).

With the subsequent code object one can execute it in a module by running `exec(code, module.__dict__)`.

New in version 3.4.

Changed in version 3.5: Made the method static.

exec_module(*module*)

Implementation of **`Loader.exec_module()`**.

New in version 3.4.

load_module(*fullname*)

Implementation of **`Loader.load_module()`**.

Deprecated since version 3.4: use **exec_module()** instead.

class importlib.abc.ExecutionLoader

An abstract base class which inherits from **InspectLoader** that, when implemented, helps a module to be executed as a script. The ABC represents an optional **PEP 302** [https://peps.python.org/pep-0302/] protocol.

abstractmethod get_filename(*fullname*)

An abstract method that is to return the value of **__file__** for the specified module. If no path is available, **ImportError** is raised.

If source code is available, then the method should return the path to the source file, regardless of whether a bytecode was used to load the module.

Changed in version 3.4: Raises **ImportError** instead of **NotImplementedError**.

class importlib.abc.FileLoader(*fullname*, *path*)

An abstract base class which inherits from **ResourceLoader** and **ExecutionLoader**, providing concrete implementations of **ResourceLoader.get_data()** and **ExecutionLoader.get_filename()**.

The *fullname* argument is a fully resolved name of the module the loader is to handle. The *path* argument is the path to the file for the module.

New in version 3.3.

name

The name of the module the loader can handle.

path

Path to the file of the module.

load_module(*fullname*)

Calls super's `load_module()`.

Deprecated since version 3.4: Use **`Loader.exec_module()`** instead.

abstractmethod get_filename(*fullname*)

Returns **`path`**.

abstractmethod get_data(*path*)

Reads *path* as a binary file and returns the bytes from it.

class importlib.abc.SourceLoader

An abstract base class for implementing source (and optionally bytecode) file loading. The class inherits from both **`ResourceLoader`** and **`ExecutionLoader`**, requiring the implementation of:

- **`ResourceLoader.get_data()`**
- **`ExecutionLoader.get_filename()`**
  Should only return the path to the source file; sourceless loading is not supported.

The abstract methods defined by this class are to add optional bytecode file support. Not implementing these optional methods (or causing them to raise **`NotImplementedError`**) causes the loader to only work with source code. Implementing the methods allows the loader to work with source *and* bytecode files; it does not allow for *sourceless* loading where only bytecode is provided. Bytecode files are an optimization to speed up loading by removing the parsing step of Python's compiler, and so no bytecode-specific API is exposed.

path_stats(*path*)

Optional abstract method which returns a **`dict`** containing metadata about the specified path.

Supported dictionary keys are:

- `'mtime'` (mandatory): an integer or floating-point number representing the modification time of the source code;
- `'size'` (optional): the size in bytes of the source code.

Any other keys in the dictionary are ignored, to allow for future extensions. If the path cannot be handled, **`OSError`** is raised.

New in version 3.3.

Changed in version 3.4: Raise **`OSError`** instead of **`NotImplementedError`**.

path_mtime(*path*)

Optional abstract method which returns the modification time for the specified path.

Deprecated since version 3.3: This method is deprecated in favour of **`path_stats()`**. You don't have to implement it, but it is still available for compatibility purposes. Raise **`OSError`** if the path cannot be handled.

Changed in version 3.4: Raise **`OSError`** instead of **`NotImplementedError`**.

set_data(*path*, *data*)

Optional abstract method which writes the specified bytes to a file path. Any intermediate directories which do not exist are to be created automatically.

When writing to the path fails because the path is read-only (**`errno.EACCES`**/**`PermissionError`**), do not propagate the exception.

Changed in version 3.4: No longer raises

NotImplementedError when called.

get_code(*fullname*)

Concrete implementation of **InspectLoader.get_code()**.

exec_module(*module*)

Concrete implementation of **Loader.exec_module()**.

New in version 3.4.

load_module(*fullname*)

Concrete implementation of **Loader.load_module()**.

Deprecated since version 3.4: Use **exec_module()** instead.

get_source(*fullname*)

Concrete implementation of **InspectLoader.get_source()**.

is_package(*fullname*)

Concrete implementation of **InspectLoader.is_package()**. A module is determined to be a package if its file path (as provided by **ExecutionLoader.get_filename()**) is a file named `__init__` when the file extension is removed **and** the module name itself does not end in `__init__`.

importlib.machinery – Importers and path hooks

Source code: Lib/importlib/machinery.py [https://github.com/python/

cpython/tree/3.11/Lib/importlib/machinery.py]

This module contains the various objects that help **`import`** find and load modules.

importlib.machinery.SOURCE_SUFFIXES

A list of strings representing the recognized file suffixes for source modules.

New in version 3.3.

importlib.machinery.DEBUG_BYTECODE_SUFFIXES

A list of strings representing the file suffixes for non-optimized bytecode modules.

New in version 3.3.

Deprecated since version 3.5: Use **`BYTECODE_SUFFIXES`** instead.

importlib.machinery.OPTIMIZED_BYTECODE_SUFFIXES

A list of strings representing the file suffixes for optimized bytecode modules.

New in version 3.3.

Deprecated since version 3.5: Use **`BYTECODE_SUFFIXES`** instead.

importlib.machinery.BYTECODE_SUFFIXES

A list of strings representing the recognized file suffixes for bytecode modules (including the leading dot).

New in version 3.3.

Changed in version 3.5: The value is no longer dependent on `__debug__`.

importlib.machinery.EXTENSION_SUFFIXES

A list of strings representing the recognized file suffixes for extension modules.

New in version 3.3.

importlib.machinery.all_suffixes()

Returns a combined list of strings representing all file suffixes for modules recognized by the standard import machinery. This is a helper for code which simply needs to know if a filesystem path potentially refers to a module without needing any details on the kind of module (for example, **`inspect.getmodulename()`**).

New in version 3.3.

class importlib.machinery.BuiltinImporter

An importer for built-in modules. All known built-in modules are listed in **`sys.builtin_module_names`**. This class implements the **`importlib.abc.MetaPathFinder`** and **`importlib.abc.InspectLoader`** ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

Changed in version 3.5: As part of **PEP 489** [https://peps.python.org/pep-0489/], the builtin importer now implements **`Loader.create_module()`** and **`Loader.exec_module()`**

class importlib.machinery.FrozenImporter

An importer for frozen modules. This class implements the **`importlib.abc.MetaPathFinder`** and **`importlib.abc.InspectLoader`** ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

Changed in version 3.4: Gained **`create_module()`** and **`exec_module()`** methods.

class importlib.machinery.WindowsRegistryFinder

Finder for modules declared in the Windows registry. This class implements the **importlib.abc.MetaPathFinder** ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

New in version 3.3.

Deprecated since version 3.6: Use **site** configuration instead. Future versions of Python may not enable this finder by default.

class importlib.machinery.PathFinder

A Finder for **sys.path** and package `__path__` attributes. This class implements the **importlib.abc.MetaPathFinder** ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

classmethod find_spec(*fullname*, *path=None*, *target=None*)

Class method that attempts to find a spec for the module specified by *fullname* on **sys.path** or, if defined, on *path*. For each path entry that is searched, **sys.path_importer_cache** is checked. If a non-false object is found then it is used as the path entry finder to look for the module being searched for. If no entry is found in **sys.path_importer_cache**, then **sys.path_hooks** is searched for a finder for the path entry and, if found, is stored in **sys.path_importer_cache** along with being queried about the module. If no finder is ever found then `None` is both stored in the cache and returned.

New in version 3.4.

Changed in version 3.5: If the current working directory – represented by an empty string – is no longer valid

then `None` is returned but no value is cached in **`sys.path_importer_cache`**.

classmethod find_module(*fullname*, *path*=*None*)

A legacy wrapper around **`find_spec()`**.

Deprecated since version 3.4: Use **`find_spec()`** instead.

classmethod invalidate_caches()

Calls **`importlib.abc.PathEntryFinder.invalidate_caches`** on all finders stored in **`sys.path_importer_cache`** that define the method. Otherwise entries in **`sys.path_importer_cache`** set to `None` are deleted.

Changed in version 3.7: Entries of `None` in **`sys.path_importer_cache`** are deleted.

Changed in version 3.4: Calls objects in **`sys.path_hooks`** with the current working directory for `''` (i.e. the empty string).

class importlib.machinery.FileFinder(*path*, **loader_details*)

A concrete implementation of **`importlib.abc.PathEntryFinder`** which caches results from the file system.

The *path* argument is the directory for which the finder is in charge of searching.

The *loader_details* argument is a variable number of 2-item tuples each containing a loader and a sequence of file suffixes the loader recognizes. The loaders are expected to be callables which accept two arguments of the module's name and the path to the file found.

The finder will cache the directory contents as necessary,

making stat calls for each module search to verify the cache is not outdated. Because cache staleness relies upon the granularity of the operating system's state information of the file system, there is a potential race condition of searching for a module, creating a new file, and then searching for the module the new file represents. If the operations happen fast enough to fit within the granularity of stat calls, then the module search will fail. To prevent this from happening, when you create a module dynamically, make sure to call **importlib.invalidate_caches()**.

New in version 3.3.

path

The path the finder will search in.

find_spec(*fullname*, *target*=*None*)

Attempt to find the spec to handle *fullname* within **path**.

New in version 3.4.

find_loader(*fullname*)

Attempt to find the loader to handle *fullname* within **path**.

Deprecated since version 3.10: Use **find_spec()** instead.

invalidate_caches()

Clear out the internal cache.

classmethod path_hook(**loader_details*)

A class method which returns a closure for use on **sys.path_hooks**. An instance of **FileFinder** is returned by the closure using the path argument given to the closure directly and *loader_details* indirectly.

If the argument to the closure is not an existing directory, **ImportError** is raised.

class importlib.machinery.SourceFileLoader(*fullname*, *path*)

A concrete implementation of **importlib.abc.SourceLoader** by subclassing **importlib.abc.FileLoader** and providing some concrete implementations of other methods.

New in version 3.3.

name

The name of the module that this loader will handle.

path

The path to the source file.

is_package(*fullname*)

Return `True` if **path** appears to be for a package.

path_stats(*path*)

Concrete implementation of **importlib.abc.SourceLoader.path_stats()**.

set_data(*path*, *data*)

Concrete implementation of **importlib.abc.SourceLoader.set_data()**.

load_module(*name=None*)

Concrete implementation of **importlib.abc.Loader.load_module()** where specifying the name of the module to load is optional.

Deprecated since version 3.6: Use **importlib.abc.Loader.exec_module()** instead.

class importlib.machinery.SourcelessFileLoader(*fullname*, *path*)

A concrete implementation of **importlib.abc.FileLoader** which can import bytecode files (i.e. no source code files exist).

Please note that direct use of bytecode files (and thus not source code files) inhibits your modules from being usable by all Python implementations or new versions of Python which change the bytecode format.

New in version 3.3.

name

The name of the module the loader will handle.

path

The path to the bytecode file.

is_package(*fullname*)

Determines if the module is a package based on **path**.

get_code(*fullname*)

Returns the code object for **name** created from **path**.

get_source(*fullname*)

Returns `None` as bytecode files have no source when this loader is used.

load_module(*name=None*)

Concrete implementation of **importlib.abc.Loader.load_module()** where specifying the name of the module to load is optional.

Deprecated since version 3.6: Use **importlib.abc.Loader.exec_module()** instead.

class importlib.machinery.ExtensionFileLoader(*fullname*, *path*)

A concrete implementation of **importlib.abc.ExecutionLoader** for extension modules.

The *fullname* argument specifies the name of the module the loader is to support. The *path* argument is the path to the extension module's file.

New in version 3.3.

name

Name of the module the loader supports.

path

Path to the extension module.

create_module(*spec*)

Creates the module object from the given specification in accordance with **PEP 489** [https://peps.python.org/pep-0489/].

New in version 3.5.

exec_module(*module*)

Initializes the given module object in accordance with **PEP 489** [https://peps.python.org/pep-0489/].

New in version 3.5.

is_package(*fullname*)

Returns `True` if the file path points to a package's `__init__` module based on **EXTENSION_SUFFIXES**.

get_code(*fullname*)

Returns `None` as extension modules lack a code object.

get_source(*fullname*)

Returns `None` as extension modules do not have source code.

get_filename(*fullname*)

Returns **`path`**.

New in version 3.4.

NamespaceLoader(name, path, path_finder):

A concrete implementation of **`importlib.abc.InspectLoader`** for namespace packages. This is an alias for a private class and is only made public for introspecting the `__loader__` attribute on namespace packages:

```
>>> from importlib.machinery import NamespaceLoader
>>> import my_namespace
>>> isinstance(my_namespace.__loader__, NamespaceLo
True
>>> import importlib.abc
>>> isinstance(my_namespace.__loader__, importlib.a
True
```

New in version 3.11.

class importlib.machinery.ModuleSpec(*name*, *loader*, ***, *origin=None*, *loader_state=None*, *is_package=None*)

A specification for a module's import-system-related state. This is typically exposed as the module's **`__spec__`** attribute. In the descriptions below, the names in parentheses give the corresponding attribute available directly on the module object, e.g. `module.__spec__.origin == module.__file__`. Note, however, that while the *values* are usually equivalent, they can differ since there is no synchronization between the two objects. For example, it is possible to update the module's **`__file__`** at runtime and this will not be automatically reflected in the module's **`__spec__.origin`**, and vice versa.

New in version 3.4.

name

(**__name__**)

The module's fully qualified name. The finder should always set this attribute to a non-empty string.

loader

(**__loader__**)

The loader used to load the module. The finder should always set this attribute.

origin

(**__file__**)

The location the loader should use to load the module. For example, for modules loaded from a .py file this is the filename. The finder should always set this attribute to a meaningful value for the loader to use. In the uncommon case that there is not one (like for namespace packages), it should be set to `None`.

submodule_search_locations

(**__path__**)

The list of locations where the package's submodules will be found. Most of the time this is a single directory. The finder should set this attribute to a list, even an empty one, to indicate to the import system that the module is a package. It should be set to `None` for non-package modules. It is set automatically later to a special object for namespace packages.

loader_state

The finder may set this attribute to an object containing additional, module-specific data to use when loading the module. Otherwise it should be set to `None`.

cached

(**`__cached__`**)

The filename of a compiled version of the module's code. The finder should always set this attribute but it may be `None` for modules that do not need compiled code stored.

parent

(**`__package__`**)

(Read-only) The fully qualified name of the package the module is in (or the empty string for a top-level module). If the module is a package then this is the same as **`name`**.

has_location

`True` if the spec's **`origin`** refers to a loadable location, `False` otherwise. This value impacts how **`origin`** is interpreted and how the module's **`__file__`** is populated.

`importlib.util` – Utility code for importers

Source code: Lib/importlib/util.py [https://github.com/python/cpython/tree/3.11/Lib/importlib/util.py]

This module contains the various objects that help in the construction of an importer.

importlib.util.MAGIC_NUMBER

The bytes which represent the bytecode version number. If you need help with loading/writing bytecode then consider

importlib.abc.SourceLoader.

New in version 3.4.

importlib.util.cache_from_source(*path*, *debug_override*=*None*, *, *optimization*=*None*)

Return the **PEP 3147** [https://peps.python.org/pep-3147/]/**PEP 488** [https://peps.python.org/pep-0488/] path to the byte-compiled file associated with the source *path*. For example, if *path* is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The `cpython-32` string comes from the current magic tag (see **get_tag()**; if **sys.implementation.cache_tag** is not defined then **NotImplementedError** will be raised).

The *optimization* parameter is used to specify the optimization level of the bytecode file. An empty string represents no optimization, so `/foo/bar/baz.py` with an *optimization* of `''` will result in a bytecode path of `/foo/bar/__pycache__/baz.cpython-32.pyc`. `None` causes the interpreter's optimization level to be used. Any other value's string representation is used, so `/foo/bar/baz.py` with an *optimization* of `2` will lead to the bytecode path of `/foo/bar/__pycache__/baz.cpython-32.opt-2.pyc`. The string representation of *optimization* can only be alphanumeric, else **ValueError** is raised.

The *debug_override* parameter is deprecated and can be used to override the system's value for `__debug__`. A `True` value is the equivalent of setting *optimization* to the empty string. A `False` value is the same as setting *optimization* to `1`. If both *debug_override* an *optimization* are not `None` then **TypeError** is raised.

New in version 3.4.

Changed in version 3.5: The *optimization* parameter was added and the *debug_override* parameter was deprecated.

Changed in version 3.6: Accepts a path-like object.

importlib.util.source_from_cache(*path*)

Given the *path* to a **PEP 3147** [https://peps.python.org/pep-3147/] file name, return the associated source code file path. For example, if *path* is `/foo/bar/__pycache__/baz.cpython-32.pyc` the returned path would be `/foo/bar/baz.py`. *path* need not exist, however if it does not conform to **PEP 3147** [https://peps.python.org/pep-3147/] or **PEP 488** [https://peps.python.org/pep-0488/] format, a **`ValueError`** is raised. If **`sys.implementation.cache_tag`** is not defined, **`NotImplementedError`** is raised.

New in version 3.4.

Changed in version 3.6: Accepts a path-like object.

importlib.util.decode_source(*source_bytes*)

Decode the given bytes representing source code and return it as a string with universal newlines (as required by **`importlib.abc.InspectLoader.get_source()`**).

New in version 3.4.

importlib.util.resolve_name(*name*, *package*)

Resolve a relative module name to an absolute one.

If **name** has no leading dots, then **name** is simply returned. This allows for usage such as `importlib.util.resolve_name('sys', __spec__.parent)` without doing a check to see if the **package** argument is needed.

`ImportError` is raised if **name** is a relative module name but **package** is a false value (e.g. `None` or the empty string). **`ImportError`** is also raised if a relative name would escape its containing package (e.g. requesting `..bacon` from within the `spam` package).

New in version 3.3.

Changed in version 3.9: To improve consistency with import

statements, raise **ImportError** instead of **ValueError** for invalid relative import attempts.

importlib.util.find_spec(*name*, *package*=*None*)

Find the spec for a module, optionally relative to the specified **package** name. If the module is in **sys.modules**, then `sys.modules[name].__spec__` is returned (unless the spec would be `None` or is not set, in which case **ValueError** is raised). Otherwise a search using **sys.meta_path** is done. `None` is returned if no spec is found.

If **name** is for a submodule (contains a dot), the parent module is automatically imported.

name and **package** work the same as for **import_module()**.

New in version 3.4.

Changed in version 3.7: Raises **ModuleNotFoundError** instead of **AttributeError** if **package** is in fact not a package (i.e. lacks a **__path__** attribute).

importlib.util.module_from_spec(*spec*)

Create a new module based on **spec** and **spec.loader.create_module**.

If **spec.loader.create_module** does not return `None`, then any pre-existing attributes will not be reset. Also, no **AttributeError** will be raised if triggered while accessing **spec** or setting an attribute on the module.

This function is preferred over using **types.ModuleType** to create a new module as **spec** is used to set as many import-controlled attributes on the module as possible.

New in version 3.5.

@importlib.util.module_for_loader

A decorator for **importlib.abc.Loader.load_module()** to handle selecting the proper module object to load with. The decorated method is expected to have a call signature taking two positional arguments (e.g. `load_module(self, module)`) for which the second argument will be the module **object** to be used by the loader. Note that the decorator will not work on static methods because of the assumption of two arguments.

The decorated method will take in the **name** of the module to be loaded as expected for a loader. If the module is not found in **sys.modules** then a new one is constructed. Regardless of where the module came from, **__loader__** set to **self** and **__package__** is set based on what **importlib.abc.InspectLoader.is_package()** returns (if available). These attributes are set unconditionally to support reloading.

If an exception is raised by the decorated method and a module was added to **sys.modules**, then the module will be removed to prevent a partially initialized module from being in left in **sys.modules**. If the module was already in **sys.modules** then it is left alone.

Changed in version 3.3: **__loader__** and **__package__** are automatically set (when possible).

Changed in version 3.4: Set **__name__**, **__loader__** **__package__** unconditionally to support reloading.

Deprecated since version 3.4: The import machinery now directly performs all the functionality provided by this function.

@importlib.util.set_loader

A decorator for **importlib.abc.Loader.load_module()** to set the **__loader__** attribute on the returned module. If the attribute is already set the decorator does nothing. It is

assumed that the first positional argument to the wrapped method (i.e. `self`) is what **`__loader__`** should be set to.

Changed in version 3.4: Set `__loader__` if set to `None`, as if the attribute does not exist.

Deprecated since version 3.4: The import machinery takes care of this automatically.

@importlib.util.set_package

A decorator for **`importlib.abc.Loader.load_module()`** to set the **`__package__`** attribute on the returned module. If **`__package__`** is set and has a value other than `None` it will not be changed.

Deprecated since version 3.4: The import machinery takes care of this automatically.

importlib.util.spec_from_loader(*name*, *loader*, ***, *origin=None*, *is_package=None*)

A factory function for creating a **`ModuleSpec`** instance based on a loader. The parameters have the same meaning as they do for ModuleSpec. The function uses available loader APIs, such as **`InspectLoader.is_package()`**, to fill in any missing information on the spec.

New in version 3.4.

importlib.util.spec_from_file_location(*name*, *location*, ***, *loader=None*, *submodule_search_locations=None*)

A factory function for creating a **`ModuleSpec`** instance based on the path to a file. Missing information will be filled in on the spec by making use of loader APIs and by the implication that the module will be file-based.

New in version 3.4.

Changed in version 3.6: Accepts a path-like object.

importlib.util.source_hash(*source_bytes*)

Return the hash of *source_bytes* as bytes. A hash-based `.pyc` file embeds the **`source_hash()`** of the corresponding source file's contents in its header.

New in version 3.7.

class importlib.util.LazyLoader(*loader*)

A class which postpones the execution of the loader of a module until the module has an attribute accessed.

This class **only** works with loaders that define **`exec_module()`** as control over what module type is used for the module is required. For those same reasons, the loader's **`create_module()`** method must return `None` or a type for which its `__class__` attribute can be mutated along with not using slots. Finally, modules which substitute the object placed into **`sys.modules`** will not work as there is no way to properly replace the module references throughout the interpreter safely; **`ValueError`** is raised if such a substitution is detected.

Note

For projects where startup time is critical, this class allows for potentially minimizing the cost of loading a module if it is never used. For projects where startup time is not essential then use of this class is **heavily** discouraged due to error messages created during loading being postponed and thus occurring out of context.

New in version 3.5.

Changed in version 3.6: Began calling **`create_module()`**, removing the compatibility warning for **`importlib.machinery.BuiltinImporter`** and **`importlib.machinery.ExtensionFileLoader`**.

classmethod factory(*loader*)

A static method which returns a callable that creates a lazy loader. This is meant to be used in situations where the loader is passed by class instead of by instance.

```
suffixes = importlib.machinery.SOURCE_SUFFIXES
loader = importlib.machinery.SourceFileLoader
lazy_loader = importlib.util.LazyLoader.factory
finder = importlib.machinery.FileFinder(path,
```

Examples

Importing programmatically

To programmatically import a module, use **`importlib.import_module()`**.

```
import importlib

itertools = importlib.import_module('itertools')
```

Checking if a module can be imported

If you need to find out if a module can be imported without actually doing the import, then you should use **`importlib.util.find_spec()`**.

Note that if `name` is a submodule (contains a dot), **`importlib.util.find_spec()`** will import the parent module.

```
import importlib.util
import sys

# For illustrative purposes.
name = 'itertools'

if name in sys.modules:
    print(f"{name!r} already in sys.modules")
elif (spec := importlib.util.find_spec(name)) is not Non
```

```
    # If you chose to perform the actual import ...
    module = importlib.util.module_from_spec(spec)
    sys.modules[name] = module
    spec.loader.exec_module(module)
    print(f"{name!r} has been imported")
else:
    print(f"can't find the {name!r} module")
```

Importing a source file directly

To import a Python source file directly, use the following recipe:

```
import importlib.util
import sys

# For illustrative purposes.
import tokenize
file_path = tokenize.__file__
module_name = tokenize.__name__

spec = importlib.util.spec_from_file_location(module_nam
module = importlib.util.module_from_spec(spec)
sys.modules[module_name] = module
spec.loader.exec_module(module)
```

Implementing lazy imports

The example below shows how to implement lazy imports:

```
>>> import importlib.util
>>> import sys
>>> def lazy_import(name):
...     spec = importlib.util.find_spec(name)
...     loader = importlib.util.LazyLoader(spec.loader)
...     spec.loader = loader
...     module = importlib.util.module_from_spec(spec)
...     sys.modules[name] = module
...     loader.exec_module(module)
...     return module
```

```
...
>>> lazy_typing = lazy_import("typing")
>>> #lazy_typing is a real module object,
>>> #but it is not loaded in memory yet.
>>> lazy_typing.TYPE_CHECKING
False
```

Setting up an importer

For deep customizations of import, you typically want to implement an importer. This means managing both the finder and loader side of things. For finders there are two flavours to choose from depending on your needs: a meta path finder or a path entry finder. The former is what you would put on **`sys.meta_path`** while the latter is what you create using a path entry hook on **`sys.path_hooks`** which works with **`sys.path`** entries to potentially create a finder. This example will show you how to register your own importers so that import will use them (for creating an importer for yourself, read the documentation for the appropriate classes defined within this package):

```
import importlib.machinery
import sys

# For illustrative purposes only.
SpamMetaPathFinder = importlib.machinery.PathFinder
SpamPathEntryFinder = importlib.machinery.FileFinder
loader_details = (importlib.machinery.SourceFileLoader,
                  importlib.machinery.SOURCE_SUFFIXES)

# Setting up a meta path finder.
# Make sure to put the finder in the proper location in
# priority.
sys.meta_path.append(SpamMetaPathFinder)

# Setting up a path entry finder.
# Make sure to put the path hook in the proper location
# of priority.
sys.path_hooks.append(SpamPathEntryFinder.path_hook(loac
```

Approximating `importlib.import_module()`

Import itself is implemented in Python code, making it possible to expose most of the import machinery through importlib. The following helps illustrate the various APIs that importlib exposes by providing an approximate implementation of `importlib.import_module()`:

```
import importlib.util
import sys

def import_module(name, package=None):
    """An approximate implementation of import."""
    absolute_name = importlib.util.resolve_name(name, pa
    try:
        return sys.modules[absolute_name]
    except KeyError:
        pass

    path = None
    if '.' in absolute_name:
        parent_name, _, child_name = absolute_name.rpart
        parent_module = import_module(parent_name)
        path = parent_module.__spec__.submodule_search_l
    for finder in sys.meta_path:
        spec = finder.find_spec(absolute_name, path)
        if spec is not None:
            break
    else:
        msg = f'No module named {absolute_name!r}'
        raise ModuleNotFoundError(msg, name=absolute_nam
    module = importlib.util.module_from_spec(spec)
    sys.modules[absolute_name] = module
    spec.loader.exec_module(module)
    if path is not None:
        setattr(parent_module, child_name, module)
    return module
```

`importlib.resources` – Resources

Source code: Lib/importlib/resources/_init_.py [https://github.com/python/cpython/tree/3.11/Lib/importlib/resources/_init_.py]

New in version 3.7.

This module leverages Python's import system to provide access to *resources* within *packages*. If you can import a package, you can access resources within that package. Resources can be opened or read, in either binary or text mode.

Resources are roughly akin to files inside directories, though it's important to keep in mind that this is just a metaphor. Resources and packages **do not** have to exist as physical files and directories on the file system: for example, a package and its resources can be imported from a zip file using `zipimport`.

Note

This module provides functionality similar to pkg_resources [https://setuptools.readthedocs.io/en/latest/pkg_resources.html] Basic Resource Access [https://setuptools.readthedocs.io/en/latest/pkg_resources.html#basic-resource-access] without the performance overhead of that package. This makes reading resources included in packages easier, with more stable and consistent semantics.

The standalone backport of this module provides more information on using importlib.resources [https://importlib-resources.readthedocs.io/en/latest/using.html] and migrating from pkg_resources to importlib.resources [https://importlib-resources.readthedocs.io/en/latest/migration.html].

Loaders that wish to support resource reading should implement a `get_resource_reader(fullname)` method as specified by **importlib.resources.abc.ResourceReader**.

importlib.resources.Package

Whenever a function accepts a `Package` argument, you can pass in either a **module object** or a module name as a string. You can only pass module objects whose `__spec__.submodule_search_locations` is not `None`.

The `Package` type is defined as `Union[str, ModuleType]`.

importlib.resources.files(*package*)

Returns a **Traversable** object representing the resource container for the package (think directory) and its resources (think files). A Traversable may contain other containers (think subdirectories).

package is either a name or a module object which conforms to the **Package** requirements.

New in version 3.9.

importlib.resources.as_file(*traversable*)

Given a **Traversable** object representing a file, typically from **importlib.resources.files()**, return a context manager for use in a **with** statement. The context manager provides a **pathlib.Path** object.

Exiting the context manager cleans up any temporary file created when the resource was extracted from e.g. a zip file.

Use `as_file` when the Traversable methods (`read_text`, etc) are insufficient and an actual file on the file system is required.

New in version 3.9.

Deprecated functions

An older, deprecated set of functions is still available, but is scheduled for removal in a future version of Python. The main drawback of these functions is that they do not support directories: they assume all resources are located directly within a *package*.

importlib.resources.Resource

For *resource* arguments of the functions below, you can pass in the name of a resource as a string or a **path-like object**.

The `Resource` type is defined as `Union[str, os.PathLike]`.

importlib.resources.open_binary(*package*, *resource*)

Open for binary reading the *resource* within *package*.

package is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). This function returns a `typing.BinaryIO` instance, a binary I/O stream open for reading.

Deprecated since version 3.11: Calls to this function can be replaced by:

```
files(package).joinpath(resource).open('rb')
```

importlib.resources.open_text(*package*, *resource*, *encoding='utf-8'*, *errors='strict'*)

Open for text reading the *resource* within *package*. By default, the resource is opened for reading as UTF-8.

package is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path

separators and it may not have sub-resources (i.e. it cannot be a directory). *encoding* and *errors* have the same meaning as with built-in **open()**.

This function returns a `typing.TextIO` instance, a text I/O stream open for reading.

Deprecated since version 3.11: Calls to this function can be replaced by:

```
files(package).joinpath(resource).open('r', encodin
```

importlib.resources.read_binary(*package*, *resource*)

Read and return the contents of the *resource* within *package* as `bytes`.

package is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). This function returns the contents of the resource as **bytes**.

Deprecated since version 3.11: Calls to this function can be replaced by:

```
files(package).joinpath(resource).read_bytes()
```

importlib.resources.read_text(*package*, *resource*, *encoding='utf-8'*, *errors='strict'*)

Read and return the contents of *resource* within *package* as a `str`. By default, the contents are read as strict UTF-8.

package is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory). *encoding* and *errors* have the same meaning as with built-in **open()**. This function returns the contents of the resource as **str**.

Deprecated since version 3.11: Calls to this function can be replaced by:

```
files(package).joinpath(resource).read_text(encodin
```

importlib.resources.path(*package*, *resource*)

Return the path to the *resource* as an actual file system path. This function returns a context manager for use in a **with** statement. The context manager provides a **pathlib.Path** object.

Exiting the context manager cleans up any temporary file created when the resource needs to be extracted from e.g. a zip file.

package is either a name or a module object which conforms to the `Package` requirements. *resource* is the name of the resource to open within *package*; it may not contain path separators and it may not have sub-resources (i.e. it cannot be a directory).

Deprecated since version 3.11: Calls to this function can be replaced using **as_file()**:

```
as_file(files(package).joinpath(resource))
```

importlib.resources.is_resource(*package*, *name*)

Return `True` if there is a resource named *name* in the package, otherwise `False`. This function does not consider directories to be resources. *package* is either a name or a module object which conforms to the `Package` requirements.

Deprecated since version 3.11: Calls to this function can be replaced by:

```
files(package).joinpath(resource).is_file()
```

importlib.resources.contents(*package*)

Return an iterable over the named items within the package. The iterable returns **`str`** resources (e.g. files) and non-resources (e.g. directories). The iterable does not recurse into subdirectories.

package is either a name or a module object which conforms to the `Package` requirements.

Deprecated since version 3.11: Calls to this function can be replaced by:

```
(resource.name for resource in files(package).iterd
```

`importlib.resources.abc` – Abstract base classes for resources

Source code: Lib/importlib/resources/abc.py [https://github.com/python/cpython/tree/3.11/Lib/importlib/resources/abc.py]

New in version 3.11.

class importlib.resources.abc.ResourceReader

Superseded by TraversableResources

An abstract base class to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored in a e.g. zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a path-like object which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the "directory". Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to

provide a method called `get_resource_reader(fullname)` which returns an object implementing this ABC's interface. If the module specified by fullname is not a package, this method should return **`None`**. An object compatible with this ABC should only be returned when the specified module is a package.

New in version 3.7.

abstractmethod open_resource(*resource*)

Returns an opened, file-like object for binary reading of the *resource*.

If the resource cannot be found, **`FileNotFoundError`** is raised.

abstractmethod resource_path(*resource*)

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise **`FileNotFoundError`**.

abstractmethod is_resource(*name*)

Returns `True` if the named *name* is considered a resource. **`FileNotFoundError`** is raised if *name* does not exist.

abstractmethod contents()

Returns an iterable of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which **`is_resource()`** would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known

that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

class importlib.resources.abc.Traversable

An object with a subset of pathlib.Path methods suitable for traversing directories and opening files.

New in version 3.9.

name

Abstract. The base name of this object without any parent references.

abstractmethod iterdir()

Yield Traversable objects in self.

abstractmethod is_dir()

Return True if self is a directory.

abstractmethod is_file()

Return True if self is a file.

abstractmethod joinpath(*child*)

Return Traversable child in self.

abstractmethod __truediv__(*child*)

Return Traversable child in self.

abstractmethod open(*mode='r', *args, **kwargs*)

mode may be 'r' or 'rb' to open as text or binary. Return a handle suitable for reading (same as **`pathlib.Path.open`**).

When opening as text, accepts encoding parameters

such as those accepted by **io.TextIOWrapper**.

read_bytes()

Read contents of self as bytes.

read_text(*encoding=None*)

Read contents of self as text.

class importlib.resources.abc.TraversableResources

An abstract base class for resource readers capable of serving the **importlib.resources.files()** interface. Subclasses **importlib.resources.abc.ResourceReader** and provides concrete implementations of the **importlib.resources.abc.ResourceReader**'s abstract methods. Therefore, any loader supplying **importlib.abc.TraversableResources** also supplies ResourceReader.

Loaders that wish to support resource reading are expected to implement this interface.

New in version 3.9.

abstractmethod files()

Returns a **importlib.resources.abc.Traversable** object for the loaded package.

Using `importlib.metadata`

New in version 3.8.

Changed in version 3.10: `importlib.metadata` is no longer provisional.

Source code: Lib/importlib/metadata/_init_.py [https://github.com/python/cpython/tree/3.11/Lib/importlib/metadata/_init_.py]

`importlib_metadata` is a library that provides access to the metadata of an installed Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package], such as its entry points or its top-level names (Import Package [https://packaging.python.org/en/latest/glossary/#term-Import-Package]s, modules, if any). Built in part on Python's import system, this library intends to replace similar functionality in the entry point API [https://setuptools.readthedocs.io/en/latest/pkg_resources.html#entry-points] and metadata API [https://setuptools.readthedocs.io/en/latest/pkg_resources.html#metadata-api] of `pkg_resources`. Along with **`importlib.resources`**, this package can eliminate the need to use the older and less efficient `pkg_resources` package.

`importlib_metadata` operates on third-party *distribution packages* installed into Python's `site-packages` directory via tools such as pip [https://pypi.org/project/pip/]. Specifically, it works with distributions with discoverable `dist-info` or `egg-info` directories, and metadata defined by the Core metadata specifications [https://packaging.python.org/en/latest/specifications/core-metadata/#core-metadata].

Important

These are *not* necessarily equivalent to or correspond 1:1 with the top-level *import package* names that can be imported inside Python code. One *distribution package* can contain multiple *import packages* (and single modules), and one top-level *import package*

may map to multiple *distribution packages* if it is a namespace package. You can use package_distributions() to get a mapping between them.

By default, distribution metadata can live on the file system or in zip archives on `sys.path`. Through an extension mechanism, the metadata can live almost anywhere.

See also

https://importlib-metadata.readthedocs.io/
: The documentation for `importlib_metadata`, which supplies a backport of `importlib.metadata`. This includes an API reference [https://importlib-metadata.readthedocs.io/en/latest/api.html] for this module's classes and functions, as well as a migration guide [https://importlib-metadata.readthedocs.io/en/latest/migration.html] for existing users of `pkg_resources`.

Overview

Let's say you wanted to get the version string for a Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] you've installed using `pip`. We start by creating a virtual environment and installing something into it:

```
$ python3 -m venv example
$ source example/bin/activate
(example) $ python -m pip install wheel
```

You can get the version string for `wheel` by running the following:

```
(example) $ python
>>> from importlib.metadata import version
>>> version('wheel')
'0.32.3'
```

You can also get a collection of entry points selectable by properties of the EntryPoint (typically 'group' or 'name'), such as

`console_scripts`, `distutils.commands` and others. Each group contains a collection of EntryPoint objects.

You can get the metadata for a distribution:

```
>>> list(metadata('wheel'))
['Metadata-Version', 'Name', 'Version', 'Summary', 'Home
```

You can also get a distribution's version number, list its constituent files, and get a list of the distribution's Distribution requirements.

Functional API

This package provides the following functionality via its public API.

Entry points

The `entry_points()` function returns a collection of entry points. Entry points are represented by `EntryPoint` instances; each `EntryPoint` has a `.name`, `.group`, and `.value` attributes and a `.load()` method to resolve the value. There are also `.module`, `.attr`, and `.extras` attributes for getting the components of the `.value` attribute.

Query all entry points:

```
>>> eps = entry_points()
```

The `entry_points()` function returns an `EntryPoints` object, a collection of all `EntryPoint` objects with `names` and `groups` attributes for convenience:

```
>>> sorted(eps.groups)
['console_scripts', 'distutils.commands', 'distutils.set
```

`EntryPoints` has a `select` method to select entry points matching specific properties. Select entry points in the `console_scripts` group:

```
>>> scripts = eps.select(group='console_scripts')
```

Equivalently, since `entry_points` passes keyword arguments through to select:

```
>>> scripts = entry_points(group='console_scripts')
```

Pick out a specific script named "wheel" (found in the wheel project):

```
>>> 'wheel' in scripts.names
True
>>> wheel = scripts['wheel']
```

Equivalently, query for that entry point during selection:

```
>>> (wheel,) = entry_points(group='console_scripts', nam
>>> (wheel,) = entry_points().select(group='console_scri
```

Inspect the resolved entry point:

```
>>> wheel
EntryPoint(name='wheel', value='wheel.cli:main', group='
>>> wheel.module
'wheel.cli'
>>> wheel.attr
'main'
>>> wheel.extras
[]
>>> main = wheel.load()
>>> main
<function main at 0x103528488>
```

The `group` and `name` are arbitrary values defined by the package author and usually a client will wish to resolve all entry points for a particular group. Read the setuptools docs [https://setuptools.pypa.io/en/latest/userguide/entry_point.html] for more information on entry points, their definition, and usage.

Compatibility Note

The "selectable" entry points were introduced in `importlib_metadata` 3.6 and Python 3.10. Prior to those

changes, `entry_points` accepted no parameters and always returned a dictionary of entry points, keyed by group. For compatibility, if no parameters are passed to entry_points, a `SelectableGroups` object is returned, implementing that dict interface. In the future, calling `entry_points` with no parameters will return an `EntryPoints` object. Users should rely on the selection interface to retrieve entry points by group.

Distribution metadata

Every Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] includes some metadata, which you can extract using the `metadata()` function:

```
>>> wheel_metadata = metadata('wheel')
```

The keys of the returned data structure, a `PackageMetadata`, name the metadata keywords, and the values are returned unparsed from the distribution metadata:

```
>>> wheel_metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

`PackageMetadata` also presents a `json` attribute that returns all the metadata in a JSON-compatible form per **PEP 566** [https://peps.python.org/pep-0566/]:

```
>>> wheel_metadata.json['requires_python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

Note

The actual type of the object returned by `metadata()` is an implementation detail and should be accessed only through the interface described by the PackageMetadata protocol [https://importlib-metadata.readthedocs.io/en/latest/api.html#importlib_metadata.PackageMetadata].

Changed in version 3.10: The `Description` is now included in the metadata when presented through the payload. Line continuation

characters have been removed.

New in version 3.10: The `json` attribute was added.

Distribution versions

The `version()` function is the quickest way to get a Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package]'s version number, as a string:

```
>>> version('wheel')
'0.32.3'
```

Distribution files

You can also get the full set of files contained within a distribution. The `files()` function takes a Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] name and returns all of the files installed by this distribution. Each file object returned is a `PackagePath`, a **`pathlib.PurePath`** derived object with additional `dist`, `size`, and `hash` properties as indicated by the metadata. For example:

```
>>> util = [p for p in files('wheel') if 'util.py' in st
>>> util
PackagePath('wheel/util.py')
>>> util.size
859
>>> util.dist
<importlib.metadata._hooks.PathDistribution object at 0x
>>> util.hash
<FileHash mode: sha256 value: bYkw5oMccfazVCoYQwKkkemoVy
```

Once you have the file, you can also read its contents:

```
>>> print(util.read_text())
import base64
import sys
...
def as_bytes(s):
```

```
    if isinstance(s, text_type):
        return s.encode('utf-8')
    return s
```

You can also use the `locate` method to get a the absolute path to the file:

```
>>> util.locate()
PosixPath('/home/gustav/example/lib/site-packages/wheel/
```

In the case where the metadata file listing files (RECORD or SOURCES.txt) is missing, `files()` will return `None`. The caller may wish to wrap calls to `files()` in always_iterable [https://more-itertools.readthedocs.io/en/stable/api.html#more_itertools.always_iterable] or otherwise guard against this condition if the target distribution is not known to have the metadata present.

Distribution requirements

To get the full set of requirements for a Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package], use the `requires()` function:

```
>>> requires('wheel')
["pytest (>=3.0.0) ; extra == 'test'", "pytest-cov ; ext
```

Mapping import to distribution packages

A convenience method to resolve the Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] name (or names, in the case of a namespace package) that provide each importable top-level Python module or Import Package [https://packaging.python.org/en/latest/glossary/#term-Import-Package]:

```
>>> packages_distributions()
{'importlib_metadata': ['importlib-metadata'], 'yaml': [
```

New in version 3.10.

Distributions

While the above API is the most common and convenient usage, you can get all of that information from the `Distribution` class. A `Distribution` is an abstract object that represents the metadata for a Python Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package]. You can get the `Distribution` instance:

```
>>> from importlib.metadata import distribution
>>> dist = distribution('wheel')
```

Thus, an alternative way to get the version number is through the `Distribution` instance:

```
>>> dist.version
'0.32.3'
```

There are all kinds of additional metadata available on the `Distribution` instance:

```
>>> dist.metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
>>> dist.metadata['License']
'MIT'
```

The full set of available metadata is not described here. See the Core metadata specifications [https://packaging.python.org/en/latest/specifications/core-metadata/#core-metadata] for additional details.

Distribution Discovery

By default, this package provides built-in support for discovery of metadata for file system and zip file Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package]s. This metadata finder search defaults to `sys.path`, but varies slightly in how it interprets those values from how other import machinery does. In particular:

- `importlib.metadata` does not honor **`bytes`** objects on `sys.path`.
- `importlib.metadata` will incidentally honor

pathlib.Path objects on `sys.path` even though such values will be ignored for imports.

Extending the search algorithm

Because Distribution Package [https://packaging.python.org/en/latest/glossary/#term-Distribution-Package] metadata is not available through **sys.path** searches, or package loaders directly, the metadata for a distribution is found through import system finders [https://docs.python.org/3/reference/import.html#finders-and-loaders]. To find a distribution package's metadata, `importlib.metadata` queries the list of meta path finders on **sys.meta_path**.

By default `importlib_metadata` installs a finder for distribution packages found on the file system. This finder doesn't actually find any *distributions*, but it can find their metadata.

The abstract class **importlib.abc.MetaPathFinder** defines the interface expected of finders by Python's import system. `importlib.metadata` extends this protocol by looking for an optional `find_distributions` callable on the finders from **sys.meta_path** and presents this extended interface as the `DistributionFinder` abstract base class, which defines this abstract method:

```
@abc.abstractmethod
def find_distributions(context=DistributionFinder.Contex
    """Return an iterable of all Distribution instances
    loading the metadata for packages for the indicated
    """
```

The `DistributionFinder.Context` object provides `.path` and `.name` properties indicating the path to search and name to match and may supply other relevant context.

What this means in practice is that to support finding distribution package metadata in locations other than the file system, subclass `Distribution` and implement the abstract methods. Then from a custom finder, return instances of this derived `Distribution` in the `find_distributions()` method.

The initialization of the `sys.path` module search path

A module search path is initialized when Python starts. This module search path may be accessed at `sys.path`.

The first entry in the module search path is the directory that contains the input script, if there is one. Otherwise, the first entry is the current directory, which is the case when executing the interactive shell, a `-c` command, or `-m` module.

The `PYTHONPATH` environment variable is often used to add directories to the search path. If this environment variable is found then the contents are added to the module search path.

Note

`PYTHONPATH` will affect all installed Python versions/ environments. Be wary of setting this in your shell profile or global environment variables. The `site` module offers more nuanced techniques as mentioned below.

The next items added are the directories containing standard Python modules as well as any extension modules that these modules depend on. Extension modules are `.pyd` files on Windows and `.so` files on other platforms. The directory with the platform-independent Python modules is called `prefix`. The directory with the extension modules is called `exec_prefix`.

The `PYTHONHOME` environment variable may be used to set the `prefix` and `exec_prefix` locations. Otherwise these directories are found by using the Python executable as a starting point and then looking for various 'landmark' files and directories. Note that any symbolic links are followed so the real Python executable location is used as the search starting point. The Python executable

location is called `home`.

Once `home` is determined, the `prefix` directory is found by first looking for `python`*`majorversionminorversion``.zip` (`python311.zip`). On Windows the zip archive is searched for in `home` and on Unix the archive is expected to be in `lib`. Note that the expected zip archive location is added to the module search path even if the archive does not exist. If no archive was found, Python on Windows will continue the search for `prefix` by looking for `Lib\os.py`. Python on Unix will look for `lib/python`*`majorversion.minorversion`*`/os.py` (`lib/python3.11/os.py`). On Windows `prefix` and `exec_prefix` are the same, however on other platforms `lib/python`*`majorversion.minorversion`*`/lib-dynload` (`lib/python3.11/lib-dynload`) is searched for and used as an anchor for `exec_prefix`. On some platforms `lib` may be `lib64` or another value, see **`sys.platlibdir`** and **`PYTHONPLATLIBDIR`**.

Once found, `prefix` and `exec_prefix` are available at **`sys.prefix`** and **`sys.exec_prefix`** respectively.

Finally, the **`site`** module is processed and `site-packages` directories are added to the module search path. A common way to customize the search path is to create **`sitecustomize`** or **`usercustomize`** modules as described in the **`site`** module documentation.

Note

Certain command line options may further affect path calculations. See **`-E`**, **`-I`**, **`-s`** and **`-S`** for further details.

Virtual environments

If Python is run in a virtual environment (as described at Virtual Environments and Packages) then `prefix` and `exec_prefix` are specific to the virtual environment.

If a `pyvenv.cfg` file is found alongside the main executable, or in the directory one level above the executable, the following variations apply:

- If `home` is an absolute path and **`PYTHONHOME`** is not set, this path is used instead of the path to the main executable when deducing `prefix` and `exec_prefix`.

_pth files

To completely override **`sys.path`** create a `._pth` file with the same name as the shared library or executable (`python._pth` or `python311._pth`). The shared library path is always known on Windows, however it may not be available on other platforms. In the `._pth` file specify one line for each path to add to **`sys.path`**. The file based on the shared library name overrides the one based on the executable, which allows paths to be restricted for any program loading the runtime if desired.

When the file exists, all registry and environment variables are ignored, isolated mode is enabled, and **`site`** is not imported unless one line in the file specifies `import site`. Blank paths and lines starting with `#` are ignored. Each path may be absolute or relative to the location of the file. Import statements other than to `site` are not permitted, and arbitrary code cannot be specified.

Note that `.pth` files (without leading underscore) will be processed normally by the **`site`** module when `import site` has been specified.

Embedded Python

If Python is embedded within another application **`Py_InitializeFromConfig()`** and the **`PyConfig`** structure can be used to initialize Python. The path specific details are described at Python Path Configuration. Alternatively the older **`Py_SetPath()`** can be used to bypass the initialization of the module search path.

Python Language Services

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

These modules include:

- **`ast`** — Abstract Syntax Trees
  - Abstract Grammar
  - Node classes
    - Literals
    - Variables
    - Expressions
      - Subscripting
      - Comprehensions
    - Statements
      - Imports
    - Control flow
    - Pattern matching
    - Function and class definitions
    - Async and await
  - **`ast`** Helpers
  - Compiler Flags
  - Command-Line Usage
- **`symtable`** — Access to the compiler's symbol tables
  - Generating Symbol Tables
  - Examining Symbol Tables

- **token** — Constants used with Python parse trees
- **keyword** — Testing for Python keywords
- **tokenize** — Tokenizer for Python source
    - Tokenizing Input
    - Command-Line Usage
    - Examples
- **tabnanny** — Detection of ambiguous indentation
- **pyclbr** — Python module browser support
    - Function Objects
    - Class Objects
- **py_compile** — Compile Python source files
    - Command-Line Interface
- **compileall** — Byte-compile Python libraries
    - Command-line use
    - Public functions
- **dis** — Disassembler for Python bytecode
    - Bytecode analysis
    - Analysis functions
    - Python Bytecode Instructions
    - Opcode collections
- **pickletools** — Tools for pickle developers
    - Command line usage
        - Command line options
    - Programmatic Interface

`ast` — Abstract Syntax Trees

Source code: Lib/ast.py [https://github.com/python/cpython/tree/3.11/Lib/ast.py]

The `ast` module helps Python applications to process trees of the Python abstract syntax grammar. The abstract syntax itself might change with each Python release; this module helps to find out programmatically what the current grammar looks like.

An abstract syntax tree can be generated by passing `ast.PyCF_ONLY_AST` as a flag to the `compile()` built-in function, or using the `parse()` helper provided in this module. The result will be a tree of objects whose classes all inherit from `ast.AST`. An abstract syntax tree can be compiled into a Python code object using the built-in `compile()` function.

Abstract Grammar

The abstract grammar is currently defined as follows:

```
-- ASDL's 4 builtin types are:
-- identifier, int, string, constant

module Python
{
    mod = Module(stmt* body, type_ignore* type_ignores)
        | Interactive(stmt* body)
        | Expression(expr body)
        | FunctionType(expr* argtypes, expr returns)

    stmt = FunctionDef(identifier name, arguments args,
                       stmt* body, expr* decorator_list,
                       string? type_comment)
```

```
    | AsyncFunctionDef(identifier name, arguments
                       stmt* body, expr* decorator
                       string? type_comment)

    | ClassDef(identifier name,
       expr* bases,
       keyword* keywords,
       stmt* body,
       expr* decorator_list)
    | Return(expr? value)

    | Delete(expr* targets)
    | Assign(expr* targets, expr value, string? ty
    | AugAssign(expr target, operator op, expr val
    -- 'simple' indicates that we annotate simple
    | AnnAssign(expr target, expr annotation, expr

    -- use 'orelse' because else is a keyword in t
    | For(expr target, expr iter, stmt* body, stmt
    | AsyncFor(expr target, expr iter, stmt* body,
    | While(expr test, stmt* body, stmt* orelse)
    | If(expr test, stmt* body, stmt* orelse)
    | With(withitem* items, stmt* body, string? ty
    | AsyncWith(withitem* items, stmt* body, strin

    | Match(expr subject, match_case* cases)

    | Raise(expr? exc, expr? cause)
    | Try(stmt* body, excepthandler* handlers, stm
    | TryStar(stmt* body, excepthandler* handlers,
    | Assert(expr test, expr? msg)

    | Import(alias* names)
    | ImportFrom(identifier? module, alias* names,

    | Global(identifier* names)
    | Nonlocal(identifier* names)
    | Expr(expr value)
```

```
        | Pass | Break | Continue

        -- col_offset is the byte offset in the utf8 s
        attributes (int lineno, int col_offset, int? e

        -- BoolOp() can use left & right?
expr = BoolOp(boolop op, expr* values)
      | NamedExpr(expr target, expr value)
      | BinOp(expr left, operator op, expr right)
      | UnaryOp(unaryop op, expr operand)
      | Lambda(arguments args, expr body)
      | IfExp(expr test, expr body, expr orelse)
      | Dict(expr* keys, expr* values)
      | Set(expr* elts)
      | ListComp(expr elt, comprehension* generators)
      | SetComp(expr elt, comprehension* generators)
      | DictComp(expr key, expr value, comprehension*
      | GeneratorExp(expr elt, comprehension* generat
      -- the grammar constrains where yield expressio
      | Await(expr value)
      | Yield(expr? value)
      | YieldFrom(expr value)

      -- x < 4 < 3 and (x < 4) < 3
      | Compare(expr left, cmpop* ops, expr* comparat
      | Call(expr func, expr* args, keyword* keywords
      | FormattedValue(expr value, int conversion, ex
      | JoinedStr(expr* values)
      | Constant(constant value, string? kind)

      -- the following expression can appear in assig
      | Attribute(expr value, identifier attr, expr_c
      | Subscript(expr value, expr slice, expr_contex
      | Starred(expr value, expr_context ctx)
      | Name(identifier id, expr_context ctx)
      | List(expr* elts, expr_context ctx)
      | Tuple(expr* elts, expr_context ctx)
```

```
      -- can appear only in Subscript
      | Slice(expr? lower, expr? upper, expr? step)

       -- col_offset is the byte offset in the utf8 s
       attributes (int lineno, int col_offset, int? e

expr_context = Load | Store | Del

boolop = And | Or

operator = Add | Sub | Mult | MatMult | Div | Mod |
             | RShift | BitOr | BitXor | BitAnd | Fl

unaryop = Invert | Not | UAdd | USub

cmpop = Eq | NotEq | Lt | LtE | Gt | GtE | Is | IsNo

comprehension = (expr target, expr iter, expr* ifs,

excepthandler = ExceptHandler(expr? type, identifier
                attributes (int lineno, int col_offs

arguments = (arg* posonlyargs, arg* args, arg? varar
             expr* kw_defaults, arg? kwarg, expr* de

arg = (identifier arg, expr? annotation, string? typ
       attributes (int lineno, int col_offset, int?

-- keyword arguments supplied to call (NULL identifi
keyword = (identifier? arg, expr value)
           attributes (int lineno, int col_offset, i

-- import name with optional 'as' alias.
alias = (identifier name, identifier? asname)
         attributes (int lineno, int col_offset, int

withitem = (expr context_expr, expr? optional_vars)
```

```
    match_case = (pattern pattern, expr? guard, stmt* bo

    pattern = MatchValue(expr value)
            | MatchSingleton(constant value)
            | MatchSequence(pattern* patterns)
            | MatchMapping(expr* keys, pattern* patterns
            | MatchClass(expr cls, pattern* patterns, id

            | MatchStar(identifier? name)
            -- The optional "rest" MatchMapping paramete

            | MatchAs(pattern? pattern, identifier? name
            | MatchOr(pattern* patterns)

             attributes (int lineno, int col_offset, int

    type_ignore = TypeIgnore(int lineno, string tag)
}
```

Node classes

class ast.AST

This is the base of all AST node classes. The actual node classes are derived from the `Parser/Python.asdl` file, which is reproduced above. They are defined in the **`_ast`** C module and re-exported in **`ast`**.

There is one class defined for each left-hand side symbol in the abstract grammar (for example, **`ast.stmt`** or **`ast.expr`**). In addition, there is one class defined for each constructor on the right-hand side; these classes inherit from the classes for the left-hand side trees. For example, **`ast.BinOp`** inherits from **`ast.expr`**. For production rules with alternatives (aka “sums”), the left-hand side class is abstract: only instances of specific constructor nodes are ever created.

_fields

Each concrete class has an attribute **_fields** which gives the names of all child nodes.

Each instance of a concrete class has one attribute for each child node, of the type as defined in the grammar. For example, **ast.BinOp** instances have an attribute **left** of type **ast.expr**.

If these attributes are marked as optional in the grammar (using a question mark), the value might be `None`. If the attributes can have zero-or-more values (marked with an asterisk), the values are represented as Python lists. All possible attributes must be present and have valid values when compiling an AST with **compile()**.

lineno
col_offset
end_lineno
end_col_offset

Instances of **ast.expr** and **ast.stmt** subclasses have **lineno**, **col_offset**, **end_lineno**, and **end_col_offset** attributes. The **lineno** and **end_lineno** are the first and last line numbers of source text span (1-indexed so the first line is line 1) and the **col_offset** and **end_col_offset** are the corresponding UTF-8 byte offsets of the first and last tokens that generated the node. The UTF-8 offset is recorded because the parser uses UTF-8 internally.

Note that the end positions are not required by the compiler and are therefore optional. The end offset is *after* the last symbol, for example one can get the source segment of a one-line expression node using `source_line[node.col_offset : node.end_col_offset]`.

The constructor of a class **ast.T** parses its arguments as follows:

- If there are positional arguments, there must be as many as there are items in **`T._fields`**; they will be assigned as attributes of these names.
- If there are keyword arguments, they will set the attributes of the same names to the given values.

For example, to create and populate an **`ast.UnaryOp`** node, you could use

```
node = ast.UnaryOp()
node.op = ast.USub()
node.operand = ast.Constant()
node.operand.value = 5
node.operand.lineno = 0
node.operand.col_offset = 0
node.lineno = 0
node.col_offset = 0
```

or the more compact

```
node = ast.UnaryOp(ast.USub(), ast.Constant(5, line
                   lineno=0, col_offset=0)
```

Changed in version 3.8: Class **`ast.Constant`** is now used for all constants.

Changed in version 3.9: Simple indices are represented by their value, extended slices are represented as tuples.

Deprecated since version 3.8: Old classes **`ast.Num`**, **`ast.Str`**, **`ast.Bytes`**, **`ast.NameConstant`** and **`ast.Ellipsis`** are still available, but they will be removed in future Python releases. In the meantime, instantiating them will return an instance of a different class.

Deprecated since version 3.9: Old classes **`ast.Index`** and **`ast.ExtSlice`** are still available, but they will be removed in future Python releases. In the meantime, instantiating them will return an instance of a different class.

Note

The descriptions of the specific node classes displayed here were initially adapted from the fantastic Green Tree Snakes [https://greentreesnakes.readthedocs.io/en/latest/] project and all its contributors.

Literals

class ast.Constant(*value*)

A constant value. The `value` attribute of the `Constant` literal contains the Python object it represents. The values represented can be simple types such as a number, string or `None`, but also immutable container types (tuples and frozensets) if all of their elements are constant.

```
>>> print(ast.dump(ast.parse('123', mode='eval'), i
Expression(
    body=Constant(value=123))
```

class ast.FormattedValue(*value*, *conversion*, *format_spec*)

Node representing a single formatting field in an f-string. If the string contains a single formatting field and nothing else the node can be isolated otherwise it appears in **`JoinedStr`**.

- `value` is any expression node (such as a literal, a variable, or a function call).
- `conversion` is an integer:
  - -1: no formatting
  - 115: `!s` string formatting
  - 114: `!r` repr formatting
  - 97: `!a` ascii formatting
- `format_spec` is a **`JoinedStr`** node representing the formatting of the value, or `None` if no format was specified. Both `conversion` and `format_spec` can be set at the same time.

class ast.JoinedStr(*values*)

An f-string, comprising a series of **`FormattedValue`** and **`Constant`** nodes.

```
>>> print(ast.dump(ast.parse('f"sin({a}) is {sin(a)
Expression(
    body=JoinedStr(
        values=[
            Constant(value='sin('),
            FormattedValue(
                value=Name(id='a', ctx=Load()),
                conversion=-1),
            Constant(value=') is '),
            FormattedValue(
                value=Call(
                    func=Name(id='sin', ctx=Load())
                    args=[
                        Name(id='a', ctx=Load())],
                    keywords=[]),
                conversion=-1,
                format_spec=JoinedStr(
                    values=[
                        Constant(value='.3')]))]))
```

class ast.List(*elts*, *ctx*)
class ast.Tuple(*elts*, *ctx*)

A list or tuple. `elts` holds a list of nodes representing the elements. `ctx` is **`Store`** if the container is an assignment target (i.e. `(x,y)=something`), and **`Load`** otherwise.

```
>>> print(ast.dump(ast.parse('[1, 2, 3]', mode='eva
Expression(
    body=List(
        elts=[
            Constant(value=1),
            Constant(value=2),
            Constant(value=3)],
        ctx=Load()))
>>> print(ast.dump(ast.parse('(1, 2, 3)', mode='eva
```

```
Expression(
    body=Tuple(
        elts=[
            Constant(value=1),
            Constant(value=2),
            Constant(value=3)],
        ctx=Load()))
```

class ast.Set(*elts*)

A set. `elts` holds a list of nodes representing the set's elements.

```
>>> print(ast.dump(ast.parse('{1, 2, 3}', mode='eva
Expression(
    body=Set(
        elts=[
            Constant(value=1),
            Constant(value=2),
            Constant(value=3)]))
```

class ast.Dict(*keys*, *values*)

A dictionary. `keys` and `values` hold lists of nodes representing the keys and the values respectively, in matching order (what would be returned when calling `dictionary.keys()` and `dictionary.values()`).

When doing dictionary unpacking using dictionary literals the expression to be expanded goes in the `values` list, with a `None` at the corresponding position in `keys`.

```
>>> print(ast.dump(ast.parse('{"a":1, **d}', mode='
Expression(
    body=Dict(
        keys=[
            Constant(value='a'),
            None],
        values=[
            Constant(value=1),
```

```
                Name(id='d', ctx=Load())]))
```

Variables

class ast.Name(*id*, *ctx*)

A variable name. `id` holds the name as a string, and `ctx` is one of the following types.

class ast.Load
class ast.Store
class ast.Del

Variable references can be used to load the value of a variable, to assign a new value to it, or to delete it. Variable references are given a context to distinguish these cases.

```
>>> print(ast.dump(ast.parse('a'), indent=4))
Module(
    body=[
        Expr(
            value=Name(id='a', ctx=Load()))],
    type_ignores=[])

>>> print(ast.dump(ast.parse('a = 1'), indent=4))
Module(
    body=[
        Assign(
            targets=[
                Name(id='a', ctx=Store())],
            value=Constant(value=1))],
    type_ignores=[])

>>> print(ast.dump(ast.parse('del a'), indent=4))
Module(
    body=[
        Delete(
            targets=[
                Name(id='a', ctx=Del())])],
    type_ignores=[])
```

class ast.Starred(*value*, *ctx*)

A `*var` variable reference. `value` holds the variable, typically a **`Name`** node. This type must be used when building a **`Call`** node with `*args`.

```
>>> print(ast.dump(ast.parse('a, *b = it'), indent=
Module(
    body=[
        Assign(
            targets=[
                Tuple(
                    elts=[
                        Name(id='a', ctx=Store()),
                        Starred(
                            value=Name(id='b', ctx=
                            ctx=Store())],
                    ctx=Store())],
            value=Name(id='it', ctx=Load()))],
    type_ignores=[])
```

Expressions

class ast.Expr(*value*)

When an expression, such as a function call, appears as a statement by itself with its return value not used or stored, it is wrapped in this container. `value` holds one of the other nodes in this section, a **`Constant`**, a **`Name`**, a **`Lambda`**, a **`Yield`** or **`YieldFrom`** node.

```
>>> print(ast.dump(ast.parse('-a'), indent=4))
Module(
    body=[
        Expr(
            value=UnaryOp(
                op=USub(),
                operand=Name(id='a', ctx=Load()))))]
    type_ignores=[])
```

class ast.UnaryOp(*op*, *operand*)

A unary operation. `op` is the operator, and `operand` any expression node.

class ast.UAdd
class ast.USub
class ast.Not
class ast.Invert

Unary operator tokens. **`Not`** is the `not` keyword, **`Invert`** is the `~` operator.

```
>>> print(ast.dump(ast.parse('not x', mode='eval'),
Expression(
    body=UnaryOp(
        op=Not(),
        operand=Name(id='x', ctx=Load())))
```

class ast.BinOp(*left*, *op*, *right*)

A binary operation (like addition or division). `op` is the operator, and `left` and `right` are any expression nodes.

```
>>> print(ast.dump(ast.parse('x + y', mode='eval'),
Expression(
    body=BinOp(
        left=Name(id='x', ctx=Load()),
        op=Add(),
        right=Name(id='y', ctx=Load()))))
```

class ast.Add
class ast.Sub
class ast.Mult
class ast.Div
class ast.FloorDiv
class ast.Mod
class ast.Pow
class ast.LShift
class ast.RShift
class ast.BitOr

class ast.BitXor
class ast.BitAnd
class ast.MatMult

Binary operator tokens.

class ast.BoolOp(*op*, *values*)

A boolean operation, ‘or’ or ‘and’. `op` is **`Or`** or **`And`**. `values` are the values involved. Consecutive operations with the same operator, such as `a or b or c`, are collapsed into one node with several values.

This doesn’t include `not`, which is a **`UnaryOp`**.

```
>>> print(ast.dump(ast.parse('x or y', mode='eval')
Expression(
    body=BoolOp(
        op=Or(),
        values=[
            Name(id='x', ctx=Load()),
            Name(id='y', ctx=Load())]))
```

class ast.And
class ast.Or

Boolean operator tokens.

class ast.Compare(*left*, *ops*, *comparators*)

A comparison of two or more values. `left` is the first value in the comparison, `ops` the list of operators, and `comparators` the list of values after the first element in the comparison.

```
>>> print(ast.dump(ast.parse('1 <= a < 10', mode='e
Expression(
    body=Compare(
        left=Constant(value=1),
        ops=[
            LtE(),
            Lt()],
```

```
            comparators=[
                Name(id='a', ctx=Load()),
                Constant(value=10)]))
```

class ast.Eq
class ast.NotEq
class ast.Lt
class ast.LtE
class ast.Gt
class ast.GtE
class ast.Is
class ast.IsNot
class ast.In
class ast.NotIn

Comparison operator tokens.

class ast.Call(*func*, *args*, *keywords*, *starargs*, *kwargs*)

A function call. `func` is the function, which will often be a **`Name`** or **`Attribute`** object. Of the arguments:

- `args` holds a list of the arguments passed by position.
- `keywords` holds a list of **`keyword`** objects representing arguments passed by keyword.

When creating a `Call` node, `args` and `keywords` are required, but they can be empty lists. `starargs` and `kwargs` are optional.

```
>>> print(ast.dump(ast.parse('func(a, b=c, *d, **e)
Expression(
    body=Call(
        func=Name(id='func', ctx=Load()),
        args=[
            Name(id='a', ctx=Load()),
            Starred(
                value=Name(id='d', ctx=Load()),
                ctx=Load())],
        keywords=[
            keyword(
```

```
                    arg='b',
                    value=Name(id='c', ctx=Load())),
                keyword(
                    value=Name(id='e', ctx=Load()))]))
```

class ast.keyword(*arg*, *value*)

A keyword argument to a function call or class definition. `arg` is a raw string of the parameter name, `value` is a node to pass in.

class ast.IfExp(*test*, *body*, *orelse*)

An expression such as `a if b else c`. Each field holds a single node, so in the following example, all three are **`Name`** nodes.

```
>>> print(ast.dump(ast.parse('a if b else c', mode=
Expression(
    body=IfExp(
        test=Name(id='b', ctx=Load()),
        body=Name(id='a', ctx=Load()),
        orelse=Name(id='c', ctx=Load())))
```

class ast.Attribute(*value*, *attr*, *ctx*)

Attribute access, e.g. `d.keys`. `value` is a node, typically a **`Name`**. `attr` is a bare string giving the name of the attribute, and `ctx` is **`Load`**, **`Store`** or **`Del`** according to how the attribute is acted on.

```
>>> print(ast.dump(ast.parse('snake.colour', mode='
Expression(
    body=Attribute(
        value=Name(id='snake', ctx=Load()),
        attr='colour',
        ctx=Load()))
```

class ast.NamedExpr(*target*, *value*)

A named expression. This AST node is

produced by the assignment expressions operator (also known as the walrus operator). As opposed to the **`Assign`** node in which the first argument can be multiple nodes, in this case both `target` and `value` must be single nodes.

```
>>> print(ast.dump(ast.parse('(x := 4)', mode='eval
Expression(
    body=NamedExpr(
        target=Name(id='x', ctx=Store()),
        value=Constant(value=4)))
```

Subscripting

class ast.Subscript(*value*, *slice*, *ctx*)

A subscript, such as `l[1]`. `value` is the subscripted object (usually sequence or mapping). `slice` is an index, slice or key. It can be a **`Tuple`** and contain a **`Slice`**. `ctx` is **`Load`**, **`Store`** or **`Del`** according to the action performed with the subscript.

```
>>> print(ast.dump(ast.parse('l[1:2, 3]', mode='eva
Expression(
    body=Subscript(
        value=Name(id='l', ctx=Load()),
        slice=Tuple(
            elts=[
                Slice(
                    lower=Constant(value=1),
                    upper=Constant(value=2)),
                Constant(value=3)],
            ctx=Load()),
        ctx=Load()))
```

class ast.Slice(*lower*, *upper*, *step*)

Regular slicing (on the form `lower:upper` or `lower:upper:step`). Can occur only inside the *slice* field of

Subscript, either directly or as an element of **Tuple**.

```
>>> print(ast.dump(ast.parse('l[1:2]', mode='eval')
Expression(
    body=Subscript(
        value=Name(id='l', ctx=Load()),
        slice=Slice(
            lower=Constant(value=1),
            upper=Constant(value=2)),
        ctx=Load()))
```

Comprehensions

class ast.ListComp(*elt*, *generators*)
class ast.SetComp(*elt*, *generators*)
class ast.GeneratorExp(*elt*, *generators*)
class ast.DictComp(*key*, *value*, *generators*)

List and set comprehensions, generator expressions, and dictionary comprehensions. `elt` (or `key` and `value`) is a single node representing the part that will be evaluated for each item.

`generators` is a list of **comprehension** nodes.

```
>>> print(ast.dump(ast.parse('[x for x in numbers]'
Expression(
    body=ListComp(
        elt=Name(id='x', ctx=Load()),
        generators=[
            comprehension(
                target=Name(id='x', ctx=Store()),
                iter=Name(id='numbers', ctx=Load())
                ifs=[],
                is_async=0)]))
>>> print(ast.dump(ast.parse('{x: x**2 for x in num
Expression(
    body=DictComp(
        key=Name(id='x', ctx=Load()),
```

```
            value=BinOp(
                left=Name(id='x', ctx=Load()),
                op=Pow(),
                right=Constant(value=2)),
            generators=[
                comprehension(
                    target=Name(id='x', ctx=Store()),
                    iter=Name(id='numbers', ctx=Load())
                    ifs=[],
                    is_async=0)]))
>>> print(ast.dump(ast.parse('{x for x in numbers}'
Expression(
    body=SetComp(
        elt=Name(id='x', ctx=Load()),
        generators=[
            comprehension(
                target=Name(id='x', ctx=Store()),
                iter=Name(id='numbers', ctx=Load())
                ifs=[],
                is_async=0)]))
```

class ast.comprehension(*target*, *iter*, *ifs*, *is_async*)

One `for` clause in a comprehension. `target` is the reference to use for each element - typically a **`Name`** or **`Tuple`** node. `iter` is the object to iterate over. `ifs` is a list of test expressions: each `for` clause can have multiple `ifs`.

`is_async` indicates a comprehension is asynchronous (using an `async for` instead of `for`). The value is an integer (0 or 1).

```
>>> print(ast.dump(ast.parse('[ord(c) for line in f
...                 indent=4)) # Multiple comprehens
Expression(
    body=ListComp(
        elt=Call(
            func=Name(id='ord', ctx=Load()),
            args=[
                Name(id='c', ctx=Load())],
```

```
            keywords=[]),
        generators=[
            comprehension(
                target=Name(id='line', ctx=Store())
                iter=Name(id='file', ctx=Load()),
                ifs=[],
                is_async=0),
            comprehension(
                target=Name(id='c', ctx=Store()),
                iter=Name(id='line', ctx=Load()),
                ifs=[],
                is_async=0)]))

>>> print(ast.dump(ast.parse('(n**2 for n in it if
...                 indent=4)) # generator comprehen
Expression(
    body=GeneratorExp(
        elt=BinOp(
            left=Name(id='n', ctx=Load()),
            op=Pow(),
            right=Constant(value=2)),
        generators=[
            comprehension(
                target=Name(id='n', ctx=Store()),
                iter=Name(id='it', ctx=Load()),
                ifs=[
                    Compare(
                        left=Name(id='n', ctx=Load(
                        ops=[
                            Gt()],
                        comparators=[
                            Constant(value=5)]),
                    Compare(
                        left=Name(id='n', ctx=Load(
                        ops=[
                            Lt()],
                        comparators=[
                            Constant(value=10)])],
```

```
                    is_async=0)]))

>>> print(ast.dump(ast.parse('[i async for i in soc
...                     indent=4)) # Async comprehension
Expression(
    body=ListComp(
        elt=Name(id='i', ctx=Load()),
        generators=[
            comprehension(
                target=Name(id='i', ctx=Store()),
                iter=Name(id='soc', ctx=Load()),
                ifs=[],
                is_async=1)]))
```

Statements

class ast.Assign(*targets*, *value*, *type_comment*)

An assignment. `targets` is a list of nodes, and `value` is a single node.

Multiple nodes in `targets` represents assigning the same value to each. Unpacking is represented by putting a **`Tuple`** or **`List`** within `targets`.

type_comment

`type_comment` is an optional string with the type annotation as a comment.

```
>>> print(ast.dump(ast.parse('a = b = 1'), indent=4
Module(
    body=[
        Assign(
            targets=[
                Name(id='a', ctx=Store()),
                Name(id='b', ctx=Store())],
            value=Constant(value=1))],
    type_ignores=[])
```

```
>>> print(ast.dump(ast.parse('a,b = c'), indent=4))
Module(
    body=[
        Assign(
            targets=[
                Tuple(
                    elts=[
                        Name(id='a', ctx=Store()),
                        Name(id='b', ctx=Store())],
                    ctx=Store())],
            value=Name(id='c', ctx=Load()))],
    type_ignores=[])
```

class ast.AnnAssign(*target*, *annotation*, *value*, *simple*)

An assignment with a type annotation. `target` is a single node and can be a **`Name`**, a **`Attribute`** or a **`Subscript`**. `annotation` is the annotation, such as a **`Constant`** or **`Name`** node. `value` is a single optional node. `simple` is a boolean integer set to True for a **`Name`** node in `target` that do not appear in between parenthesis and are hence pure names and not expressions.

```
>>> print(ast.dump(ast.parse('c: int'), indent=4))
Module(
    body=[
        AnnAssign(
            target=Name(id='c', ctx=Store()),
            annotation=Name(id='int', ctx=Load()),
            simple=1)],
    type_ignores=[])

>>> print(ast.dump(ast.parse('(a): int = 1'), inden
Module(
    body=[
        AnnAssign(
            target=Name(id='a', ctx=Store()),
            annotation=Name(id='int', ctx=Load()),
            value=Constant(value=1),
```

```
                simple=0)],
        type_ignores=[])

>>> print(ast.dump(ast.parse('a.b: int'), indent=4))
Module(
    body=[
        AnnAssign(
            target=Attribute(
                value=Name(id='a', ctx=Load()),
                attr='b',
                ctx=Store()),
            annotation=Name(id='int', ctx=Load()),
            simple=0)],
    type_ignores=[])

>>> print(ast.dump(ast.parse('a[1]: int'), indent=4
Module(
    body=[
        AnnAssign(
            target=Subscript(
                value=Name(id='a', ctx=Load()),
                slice=Constant(value=1),
                ctx=Store()),
            annotation=Name(id='int', ctx=Load()),
            simple=0)],
    type_ignores=[])
```

class ast.AugAssign(*target*, *op*, *value*)

Augmented assignment, such as `a += 1`. In the following example, `target` is a **`Name`** node for `x` (with the **`Store`** context), `op` is **`Add`**, and `value` is a **`Constant`** with value for 1.

The `target` attribute cannot be of class **`Tuple`** or **`List`**, unlike the targets of **`Assign`**.

```
>>> print(ast.dump(ast.parse('x += 2'), indent=4))
Module(
    body=[
```

```
            AugAssign(
                target=Name(id='x', ctx=Store()),
                op=Add(),
                value=Constant(value=2))],
        type_ignores=[])
```

class ast.Raise(*exc*, *cause*)

A `raise` statement. `exc` is the exception object to be raised, normally a **`Call`** or **`Name`**, or `None` for a standalone `raise`. `cause` is the optional part for `y` in `raise x from y`.

```
>>> print(ast.dump(ast.parse('raise x from y'), ind
Module(
    body=[
        Raise(
            exc=Name(id='x', ctx=Load()),
            cause=Name(id='y', ctx=Load()))],
    type_ignores=[])
```

class ast.Assert(*test*, *msg*)

An assertion. `test` holds the condition, such as a **`Compare`** node. `msg` holds the failure message.

```
>>> print(ast.dump(ast.parse('assert x,y'), indent=
Module(
    body=[
        Assert(
            test=Name(id='x', ctx=Load()),
            msg=Name(id='y', ctx=Load()))],
    type_ignores=[])
```

class ast.Delete(*targets*)

Represents a `del` statement. `targets` is a list of nodes, such as **`Name`**, **`Attribute`** or **`Subscript`** nodes.

```
>>> print(ast.dump(ast.parse('del x,y,z'), indent=4
Module(
```

```
        body=[
            Delete(
                targets=[
                    Name(id='x', ctx=Del()),
                    Name(id='y', ctx=Del()),
                    Name(id='z', ctx=Del())])],
        type_ignores=[])
```

class ast.Pass

A `pass` statement.

```
>>> print(ast.dump(ast.parse('pass'), indent=4))
Module(
    body=[
        Pass()],
    type_ignores=[])
```

Other statements which are only applicable inside functions or loops are described in other sections.

Imports

class ast.Import(*names*)

An import statement. `names` is a list of **`alias`** nodes.

```
>>> print(ast.dump(ast.parse('import x,y,z'), inden
Module(
    body=[
        Import(
            names=[
                alias(name='x'),
                alias(name='y'),
                alias(name='z')])],
    type_ignores=[])
```

class ast.ImportFrom(*module*, *names*, *level*)

Represents `from x import y`. `module` is a raw string of the 'from' name, without any leading dots, or `None` for

statements such as `from . import foo`. `level` is an integer holding the level of the relative import (0 means absolute import).

```
>>> print(ast.dump(ast.parse('from y import x,y,z')
Module(
    body=[
        ImportFrom(
            module='y',
            names=[
                alias(name='x'),
                alias(name='y'),
                alias(name='z')],
            level=0)],
    type_ignores=[])
```

class ast.alias(*name*, *asname*)

Both parameters are raw strings of the names. `asname` can be `None` if the regular name is to be used.

```
>>> print(ast.dump(ast.parse('from ..foo.bar import
Module(
    body=[
        ImportFrom(
            module='foo.bar',
            names=[
                alias(name='a', asname='b'),
                alias(name='c')],
            level=2)],
    type_ignores=[])
```

Control flow

Note

Optional clauses such as `else` are stored as an empty list if they're not present.

class ast.If(*test*, *body*, *orelse*)

An `if` statement. `test` holds a single node, such as a **`Compare`** node. `body` and `orelse` each hold a list of nodes.

`elif` clauses don't have a special representation in the AST, but rather appear as extra **`If`** nodes within the `orelse` section of the previous one.

```
>>> print(ast.dump(ast.parse("""
... if x:
...     ...
... elif y:
...     ...
... else:
...     ...
... """), indent=4))
Module(
    body=[
        If(
            test=Name(id='x', ctx=Load()),
            body=[
                Expr(
                    value=Constant(value=Ellipsis))
            orelse=[
                If(
                    test=Name(id='y', ctx=Load()),
                    body=[
                        Expr(
                            value=Constant(value=El
                    orelse=[
                        Expr(
                            value=Constant(value=El
    type_ignores=[])
```

class ast.For(*target*, *iter*, *body*, *orelse*, *type_comment*)

A `for` loop. `target` holds the variable(s) the loop assigns to, as a single **`Name`**, **`Tuple`** or **`List`** node. `iter` holds the item to be looped over, again as a single node. `body` and

`orelse` contain lists of nodes to execute. Those in `orelse` are executed if the loop finishes normally, rather than via a `break` statement.

type_comment

`type_comment` is an optional string with the type annotation as a comment.

```
>>> print(ast.dump(ast.parse("""
... for x in y:
...     ...
... else:
...     ...
... """), indent=4))
Module(
    body=[
        For(
            target=Name(id='x', ctx=Store()),
            iter=Name(id='y', ctx=Load()),
            body=[
                Expr(
                    value=Constant(value=Ellipsis))
            orelse=[
                Expr(
                    value=Constant(value=Ellipsis))
    type_ignores=[])
```

class ast.While(*test*, *body*, *orelse*)

A `while` loop. `test` holds the condition, such as a **`Compare`** node.

```
>> print(ast.dump(ast.parse("""
... while x:
...     ...
... else:
...     ...
... """), indent=4))
Module(
```

```
        body=[
            While(
                test=Name(id='x', ctx=Load()),
                body=[
                    Expr(
                        value=Constant(value=Ellipsis))
                orelse=[
                    Expr(
                        value=Constant(value=Ellipsis))
        type_ignores=[])
```

class ast.Break
class ast.Continue

The `break` and `continue` statements.

```
>>> print(ast.dump(ast.parse("""\
... for a in b:
...     if a > 5:
...         break
...     else:
...         continue
...
... """), indent=4))
Module(
    body=[
        For(
            target=Name(id='a', ctx=Store()),
            iter=Name(id='b', ctx=Load()),
            body=[
                If(
                    test=Compare(
                        left=Name(id='a', ctx=Load(
                        ops=[
                            Gt()],
                        comparators=[
                            Constant(value=5)]),
                    body=[
                        Break()],
```

```
                        orelse=[
                            Continue()])],
                orelse=[])],
        type_ignores=[])
```

class ast.Try(*body*, *handlers*, *orelse*, *finalbody*)

`try` blocks. All attributes are list of nodes to execute, except for `handlers`, which is a list of **`ExceptHandler`** nodes.

```
>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except Exception:
...     ...
... except OtherException as e:
...     ...
... else:
...     ...
... finally:
...     ...
... """), indent=4))
Module(
    body=[
        Try(
            body=[
                Expr(
                    value=Constant(value=Ellipsis))
            handlers=[
                ExceptHandler(
                    type=Name(id='Exception', ctx=L
                    body=[
                        Expr(
                            value=Constant(value=El
                ExceptHandler(
                    type=Name(id='OtherException',
                    name='e',
                    body=[
                        Expr(
```

```
                                    value=Constant(value=El
                orelse=[
                    Expr(
                        value=Constant(value=Ellipsis))
                finalbody=[
                    Expr(
                        value=Constant(value=Ellipsis))
        type_ignores=[])
```

class ast.TryStar(*body*, *handlers*, *orelse*, *finalbody*)

`try` blocks which are followed by `except*` clauses. The attributes are the same as for **`Try`** but the **`ExceptHandler`** nodes in `handlers` are interpreted as `except*` blocks rather then `except`.

```
>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except* Exception:
...     ...
... """), indent=4))
Module(
    body=[
        TryStar(
            body=[
                Expr(
                    value=Constant(value=Ellipsis))
            handlers=[
                ExceptHandler(
                    type=Name(id='Exception', ctx=L
                    body=[
                        Expr(
                            value=Constant(value=El
            orelse=[],
            finalbody=[])],
    type_ignores=[])
```

class ast.ExceptHandler(*type*, *name*, *body*)

A single `except` clause. `type` is the exception type it will match, typically a **`Name`** node (or `None` for a catch-all `except:` clause). `name` is a raw string for the name to hold the exception, or `None` if the clause doesn't have `as foo`. `body` is a list of nodes.

```
>>> print(ast.dump(ast.parse("""\
... try:
...     a + 1
... except TypeError:
...     pass
... """), indent=4))
Module(
    body=[
        Try(
            body=[
                Expr(
                    value=BinOp(
                        left=Name(id='a', ctx=Load(
                        op=Add(),
                        right=Constant(value=1)))],
            handlers=[
                ExceptHandler(
                    type=Name(id='TypeError', ctx=L
                    body=[
                        Pass()])],
            orelse=[],
            finalbody=[])],
    type_ignores=[])
```

class ast.With(*items*, *body*, *type_comment*)

A `with` block. `items` is a list of **`withitem`** nodes representing the context managers, and `body` is the indented block inside the context.

type_comment

`type_comment` is an optional string with the type annotation as a comment.

class ast.withitem(*context_expr*, *optional_vars*)

A single context manager in a `with` block. `context_expr` is the context manager, often a **`Call`** node. `optional_vars` is a **`Name`**, **`Tuple`** or **`List`** for the `as foo` part, or `None` if that isn't used.

```
>>> print(ast.dump(ast.parse("""\
... with a as b, c as d:
...     something(b, d)
... """), indent=4))
Module(
    body=[
        With(
            items=[
                withitem(
                    context_expr=Name(id='a', ctx=L
                    optional_vars=Name(id='b', ctx=
                withitem(
                    context_expr=Name(id='c', ctx=L
                    optional_vars=Name(id='d', ctx=
            body=[
                Expr(
                    value=Call(
                        func=Name(id='something', c
                        args=[
                            Name(id='b', ctx=Load()
                            Name(id='d', ctx=Load()
                        keywords=[]))])],
    type_ignores=[])
```

Pattern matching

class ast.Match(*subject*, *cases*)

A `match` statement. `subject` holds the subject of the match (the object that is being matched against the cases) and `cases` contains an iterable of **`match_case`** nodes with the different cases.

class ast.match_case(*pattern*, *guard*, *body*)

A single case pattern in a `match` statement. `pattern` contains the match pattern that the subject will be matched against. Note that the **`AST`** nodes produced for patterns differ from those produced for expressions, even when they share the same syntax.

The `guard` attribute contains an expression that will be evaluated if the pattern matches the subject.

`body` contains a list of nodes to execute if the pattern matches and the result of evaluating the guard expression is true.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] if x>0:
...         ...
...     case tuple():
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchSequence(
                        patterns=[
                            MatchAs(name='x')]),
                    guard=Compare(
                        left=Name(id='x', ctx=Load(
                        ops=[
                            Gt()],
                        comparators=[
                            Constant(value=0)]),
                    body=[
                        Expr(
                            value=Constant(value=El
```

```
                    match_case(
                        pattern=MatchClass(
                            cls=Name(id='tuple', ctx=Lo
                            patterns=[],
                            kwd_attrs=[],
                            kwd_patterns=[]),
                        body=[
                            Expr(
                                value=Constant(value=El
        type_ignores=[])
```

class ast.MatchValue(*value*)

A match literal or value pattern that compares by equality. `value` is an expression node. Permitted value nodes are restricted as described in the match statement documentation. This pattern succeeds if the match subject is equal to the evaluated value.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case "Relevant":
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchValue(
                        value=Constant(value='Relev
                    body=[
                        Expr(
                            value=Constant(value=El
    type_ignores=[])
```

class ast.MatchSingleton(*value*)

A match literal pattern that compares by identity. `value` is

the singleton to be compared against: `None`, `True`, or `False`. This pattern succeeds if the match subject is the given constant.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case None:
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchSingleton(value=No
                    body=[
                        Expr(
                            value=Constant(value=El
    type_ignores=[])
```

class ast.MatchSequence(*patterns*)

A match sequence pattern. `patterns` contains the patterns to be matched against the subject elements if the subject is a sequence. Matches a variable length sequence if one of the subpatterns is a `MatchStar` node, otherwise matches a fixed length sequence.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [1, 2]:
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
```

```
                        pattern=MatchSequence(
                            patterns=[
                                MatchValue(
                                    value=Constant(valu
                                MatchValue(
                                    value=Constant(valu
                        body=[
                            Expr(
                                value=Constant(value=El
        type_ignores=[])
```

class ast.MatchStar(*name*)

Matches the rest of the sequence in a variable length match sequence pattern. If `name` is not `None`, a list containing the remaining sequence elements is bound to that name if the overall sequence pattern is successful.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [1, 2, *rest]:
...         ...
...     case [*_]:
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchSequence(
                        patterns=[
                            MatchValue(
                                value=Constant(valu
                            MatchValue(
                                value=Constant(valu
                            MatchStar(name='rest')]
                    body=[
```

```
                            Expr(
                                value=Constant(value=El
                    match_case(
                        pattern=MatchSequence(
                            patterns=[
                                MatchStar()]),
                        body=[
                            Expr(
                                value=Constant(value=El
        type_ignores=[])
```

class ast.MatchMapping(*keys*, *patterns*, *rest*)

A match mapping pattern. `keys` is a sequence of expression nodes. `patterns` is a corresponding sequence of pattern nodes. `rest` is an optional name that can be specified to capture the remaining mapping elements. Permitted key expressions are restricted as described in the match statement documentation.

This pattern succeeds if the subject is a mapping, all evaluated key expressions are present in the mapping, and the value corresponding to each key matches the corresponding subpattern. If `rest` is not `None`, a dict containing the remaining mapping elements is bound to that name if the overall mapping pattern is successful.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case {1: _, 2: _}:
...         ...
...     case {**rest}:
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
```

```
                        pattern=MatchMapping(
                            keys=[
                                Constant(value=1),
                                Constant(value=2)],
                            patterns=[
                                MatchAs(),
                                MatchAs()]),
                        body=[
                            Expr(
                                value=Constant(value=El
                    match_case(
                        pattern=MatchMapping(keys=[], p
                        body=[
                            Expr(
                                value=Constant(value=El
    type_ignores=[])
```

class ast.MatchClass(*cls*, *patterns*, *kwd_attrs*, *kwd_patterns*)

A match class pattern. `cls` is an expression giving the nominal class to be matched. `patterns` is a sequence of pattern nodes to be matched against the class defined sequence of pattern matching attributes. `kwd_attrs` is a sequence of additional attributes to be matched (specified as keyword arguments in the class pattern), `kwd_patterns` are the corresponding patterns (specified as keyword values in the class pattern).

This pattern succeeds if the subject is an instance of the nominated class, all positional patterns match the corresponding class-defined attributes, and any specified keyword attributes match their corresponding pattern.

Note: classes may define a property that returns self in order to match a pattern node against the instance being matched. Several builtin types are also matched that way, as described in the match statement documentation.

```
>>> print(ast.dump(ast.parse("""
... match x:
```

```
...     case Point2D(0, 0):
...         ...
...     case Point3D(x=0, y=0, z=0):
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchClass(
                        cls=Name(id='Point2D', ctx=
                        patterns=[
                            MatchValue(
                                value=Constant(valu
                            MatchValue(
                                value=Constant(valu
                        kwd_attrs=[],
                        kwd_patterns=[]),
                    body=[
                        Expr(
                            value=Constant(value=El
                match_case(
                    pattern=MatchClass(
                        cls=Name(id='Point3D', ctx=
                        patterns=[],
                        kwd_attrs=[
                            'x',
                            'y',
                            'z'],
                        kwd_patterns=[
                            MatchValue(
                                value=Constant(valu
                            MatchValue(
                                value=Constant(valu
                            MatchValue(
                                value=Constant(valu
```

```
                        body=[
                            Expr(
                                value=Constant(value=El
        type_ignores=[])
```

class ast.MatchAs(*pattern*, *name*)

A match “as-pattern”, capture pattern or wildcard pattern. `pattern` contains the match pattern that the subject will be matched against. If the pattern is `None`, the node represents a capture pattern (i.e a bare name) and will always succeed.

The `name` attribute contains the name that will be bound if the pattern is successful. If `name` is `None`, `pattern` must also be `None` and the node represents the wildcard pattern.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] as y:
...         ...
...     case _:
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchAs(
                        pattern=MatchSequence(
                            patterns=[
                                MatchAs(name='x')])
                        name='y'),
                    body=[
                        Expr(
                            value=Constant(value=El
                match_case(
                    pattern=MatchAs(),
                    body=[
```

```
                                Expr(
                                    value=Constant(value=El
        type_ignores=[])
```

class ast.MatchOr(*patterns*)

A match “or-pattern”. An or-pattern matches each of its subpatterns in turn to the subject, until one succeeds. The or-pattern is then deemed to succeed. If none of the subpatterns succeed the or-pattern fails. The `patterns` attribute contains a list of match pattern nodes that will be matched against the subject.

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] | (y):
...         ...
... """), indent=4))
Module(
    body=[
        Match(
            subject=Name(id='x', ctx=Load()),
            cases=[
                match_case(
                    pattern=MatchOr(
                        patterns=[
                            MatchSequence(
                                patterns=[
                                    MatchAs(name='x
                            MatchAs(name='y')]),
                    body=[
                        Expr(
                            value=Constant(value=El
        type_ignores=[])
```

Function and class definitions

class ast.FunctionDef(*name*, *args*, *body*, *decorator_list*, *returns*, *type_comment*)

A function definition.

- `name` is a raw string of the function name.
- `args` is an **`arguments`** node.
- `body` is the list of nodes inside the function.
- `decorator_list` is the list of decorators to be applied, stored outermost first (i.e. the first in the list will be applied last).
- `returns` is the return annotation.

type_comment

`type_comment` is an optional string with the type annotation as a comment.

class ast.Lambda(*args*, *body*)

`lambda` is a minimal function definition that can be used inside an expression. Unlike **`FunctionDef`**, `body` holds a single node.

```
>>> print(ast.dump(ast.parse('lambda x,y: ...'), in
Module(
    body=[
        Expr(
            value=Lambda(
                args=arguments(
                    posonlyargs=[],
                    args=[
                        arg(arg='x'),
                        arg(arg='y')],
                    kwonlyargs=[],
                    kw_defaults=[],
                    defaults=[]),
                body=Constant(value=Ellipsis)))],
    type_ignores=[])
```

class ast.arguments(*posonlyargs*, *args*, *vararg*, *kwonlyargs*, *kw_defaults*, *kwarg*, *defaults*)

The arguments for a function.

- `posonlyargs`, `args` and `kwonlyargs` are lists of **`arg`** nodes.
- `vararg` and `kwarg` are single **`arg`** nodes, referring to the `*args`, `**kwargs` parameters.
- `kw_defaults` is a list of default values for keyword-only arguments. If one is `None`, the corresponding argument is required.
- `defaults` is a list of default values for arguments that can be passed positionally. If there are fewer defaults, they correspond to the last n arguments.

class ast.arg(*arg*, *annotation*, *type_comment*)

A single argument in a list. `arg` is a raw string of the argument name, `annotation` is its annotation, such as a **`Str`** or **`Name`** node.

type_comment

`type_comment` is an optional string with the type annotation as a comment

```
>>> print(ast.dump(ast.parse("""\
... @decorator1
... @decorator2
... def f(a: 'annotation', b=1, c=2, *d, e, f=3, **
...     pass
... """), indent=4))
Module(
    body=[
        FunctionDef(
            name='f',
            args=arguments(
                posonlyargs=[],
                args=[
                    arg(
                        arg='a',
                        annotation=Constant(value='
                    arg(arg='b'),
                    arg(arg='c')],
```

```
                    vararg=arg(arg='d'),
                    kwonlyargs=[
                        arg(arg='e'),
                        arg(arg='f')],
                    kw_defaults=[
                        None,
                        Constant(value=3)],
                    kwarg=arg(arg='g'),
                    defaults=[
                        Constant(value=1),
                        Constant(value=2)]),
                body=[
                    Pass()],
                decorator_list=[
                    Name(id='decorator1', ctx=Load()),
                    Name(id='decorator2', ctx=Load())],
                returns=Constant(value='return annotati
        type_ignores=[])
```

class ast.Return(*value*)

A `return` statement.

```
>>> print(ast.dump(ast.parse('return 4'), indent=4))
Module(
    body=[
        Return(
            value=Constant(value=4))],
    type_ignores=[])
```

class ast.Yield(*value*)

class ast.YieldFrom(*value*)

A `yield` or `yield from` expression. Because these are expressions, they must be wrapped in a **`Expr`** node if the value sent back is not used.

```
>>> print(ast.dump(ast.parse('yield x'), indent=4))
Module(
    body=[
```

```
            Expr(
                value=Yield(
                    value=Name(id='x', ctx=Load()))),
        type_ignores=[])

    >>> print(ast.dump(ast.parse('yield from x'), inden
    Module(
        body=[
            Expr(
                value=YieldFrom(
                    value=Name(id='x', ctx=Load()))),
        type_ignores=[])
```

class ast.Global(*names*)

class ast.Nonlocal(*names*)

`global` and `nonlocal` statements. `names` is a list of raw strings.

```
    >>> print(ast.dump(ast.parse('global x,y,z'), inden
    Module(
        body=[
            Global(
                names=[
                    'x',
                    'y',
                    'z'])],
        type_ignores=[])

    >>> print(ast.dump(ast.parse('nonlocal x,y,z'), ind
    Module(
        body=[
            Nonlocal(
                names=[
                    'x',
                    'y',
                    'z'])],
        type_ignores=[])
```

class ast.ClassDef(*name*, *bases*, *keywords*, *starargs*, *kwargs*, *body*, *decorator_list*)

A class definition.

- `name` is a raw string for the class name
- `bases` is a list of nodes for explicitly specified base classes.
- `keywords` is a list of **`keyword`** nodes, principally for 'metaclass'. Other keywords will be passed to the metaclass, as per PEP-3115 [https://peps.python.org/pep-3115/].
- `starargs` and `kwargs` are each a single node, as in a function call. starargs will be expanded to join the list of base classes, and kwargs will be passed to the metaclass.
- `body` is a list of nodes representing the code within the class definition.
- `decorator_list` is a list of nodes, as in **`FunctionDef`**.

```
>>> print(ast.dump(ast.parse("""\
... @decorator1
... @decorator2
... class Foo(base1, base2, metaclass=meta):
...     pass
... """), indent=4))
Module(
    body=[
        ClassDef(
            name='Foo',
            bases=[
                Name(id='base1', ctx=Load()),
                Name(id='base2', ctx=Load())],
            keywords=[
                keyword(
                    arg='metaclass',
                    value=Name(id='meta', ctx=Load(
            body=[
                Pass()],
```

```
                decorator_list=[
                    Name(id='decorator1', ctx=Load()),
                    Name(id='decorator2', ctx=Load())])
        type_ignores=[])
```

Async and await

class ast.AsyncFunctionDef(*name*, *args*, *body*, *decorator_list*, *returns*, *type_comment*)

An `async def` function definition. Has the same fields as **`FunctionDef`**.

class ast.Await(*value*)

An `await` expression. `value` is what it waits for. Only valid in the body of an **`AsyncFunctionDef`**.

```
>>> print(ast.dump(ast.parse("""\
... async def f():
...     await other_func()
... """), indent=4))
Module(
    body=[
        AsyncFunctionDef(
            name='f',
            args=arguments(
                posonlyargs=[],
                args=[],
                kwonlyargs=[],
                kw_defaults=[],
                defaults=[]),
            body=[
                Expr(
                    value=Await(
                        value=Call(
                            func=Name(id='other_func', c
                            args=[],
                            keywords=[])))],
```

```
            decorator_list=[])],
    type_ignores=[])
```

class ast.AsyncFor(*target*, *iter*, *body*, *orelse*, *type_comment*)

class ast.AsyncWith(*items*, *body*, *type_comment*)

`async for` loops and `async with` context managers. They have the same fields as **`For`** and **`With`**, respectively. Only valid in the body of an **`AsyncFunctionDef`**.

Note

When a string is parsed by **`ast.parse()`**, operator nodes (subclasses of **`ast.operator`**, **`ast.unaryop`**, **`ast.cmpop`**, **`ast.boolop`** and **`ast.expr_context`**) on the returned tree will be singletons. Changes to one will be reflected in all other occurrences of the same value (e.g. **`ast.Add`**).

`ast` Helpers

Apart from the node classes, the **`ast`** module defines these utility functions and classes for traversing abstract syntax trees:

ast.parse(*source*, *filename='<unknown>'*, *mode='exec'*, ***, *type_comments=False*, *feature_version=None*)

Parse the source into an AST node. Equivalent to `compile(source, filename, mode, ast.PyCF_ONLY_AST)`.

If `type_comments=True` is given, the parser is modified to check and return type comments as specified by **PEP 484** [https://peps.python.org/pep-0484/] and **PEP 526** [https://peps.python.org/pep-0526/]. This is equivalent to adding **`ast.PyCF_TYPE_COMMENTS`** to the flags passed to **`compile()`**. This will report syntax errors for misplaced type comments. Without this flag, type comments will be ignored, and the `type_comment` field on selected AST nodes will always be `None`. In addition, the locations of `# type: ignore` comments will be returned as the `type_ignores`

attribute of **Module** (otherwise it is always an empty list).

In addition, if `mode` is `'func_type'`, the input syntax is modified to correspond to **PEP 484** [https://peps.python.org/pep-0484/] "signature type comments", e.g. `(str, int) -> List[str]`.

Also, setting `feature_version` to a tuple `(major, minor)` will attempt to parse using that Python version's grammar. Currently `major` must equal to `3`. For example, setting `feature_version=(3, 4)` will allow the use of `async` and `await` as variable names. The lowest supported version is `(3, 4)`; the highest is `sys.version_info[0:2]`.

If source contains a null character ('0'), **ValueError** is raised.

Warning

Note that successfully parsing source code into an AST object doesn't guarantee that the source code provided is valid Python code that can be executed as the compilation step can raise further **SyntaxError** exceptions. For instance, the source `return 42` generates a valid AST node for a return statement, but it cannot be compiled alone (it needs to be inside a function node).

In particular, **ast.parse()** won't do any scoping checks, which the compilation step does.

Warning

It is possible to crash the Python interpreter with a sufficiently large/complex string due to stack depth limitations in Python's AST compiler.

Changed in version 3.8: Added `type_comments`, `mode='func_type'` and `feature_version`.

ast.unparse(*ast_obj*)

Unparse an **ast.AST** object and generate a string with code that would produce an equivalent **ast.AST** object if parsed back with **ast.parse()**.

Warning

The produced code string will not necessarily be equal to the original code that generated the **ast.AST** object (without any compiler optimizations, such as constant tuples/frozensets).

Warning

Trying to unparse a highly complex expression would result with **RecursionError**.

New in version 3.9.

ast.literal_eval(*node_or_string*)

Evaluate an expression node or a string containing only a Python literal or container display. The string or node provided may only consist of the following Python literal structures: strings, bytes, numbers, tuples, lists, dicts, sets, booleans, `None` and `Ellipsis`.

This can be used for evaluating strings containing Python values without the need to parse the values oneself. It is not capable of evaluating arbitrarily complex expressions, for example involving operators or indexing.

This function had been documented as “safe” in the past without defining what that meant. That was misleading. This is specifically designed not to execute Python code, unlike the more general **eval()**. There is no namespace, no name lookups, or ability to call out. But it is not free from attack: A relatively small input can lead to memory exhaustion or to C stack exhaustion, crashing the process. There is also the possibility for excessive CPU consumption denial of service on

some inputs. Calling it on untrusted data is thus not recommended.

Warning

It is possible to crash the Python interpreter due to stack depth limitations in Python's AST compiler.

It can raise **ValueError**, **TypeError**, **SyntaxError**, **MemoryError** and **RecursionError** depending on the malformed input.

Changed in version 3.2: Now allows bytes and set literals.

Changed in version 3.9: Now supports creating empty sets with `'set()'`.

Changed in version 3.10: For string inputs, leading spaces and tabs are now stripped.

ast.get_docstring(*node*, *clean=True*)

Return the docstring of the given *node* (which must be a **FunctionDef**, **AsyncFunctionDef**, **ClassDef**, or **Module** node), or `None` if it has no docstring. If *clean* is true, clean up the docstring's indentation with **inspect.cleandoc()**.

Changed in version 3.5: **AsyncFunctionDef** is now supported.

ast.get_source_segment(*source*, *node*, ***, *padded=False*)

Get source code segment of the *source* that generated *node*. If some location information (**lineno**, **end_lineno**, **col_offset**, or **end_col_offset**) is missing, return `None`.

If *padded* is `True`, the first line of a multi-line statement will be padded with spaces to match its original position.

New in version 3.8.

ast.fix_missing_locations(*node*)

When you compile a node tree with **compile()**, the compiler expects **lineno** and **col_offset** attributes for every node that supports them. This is rather tedious to fill in for generated nodes, so this helper adds these attributes recursively where not already set, by setting them to the values of the parent node. It works recursively starting at *node*.

ast.increment_lineno(*node*, *n=1*)

Increment the line number and end line number of each node in the tree starting at *node* by *n*. This is useful to "move code" to a different location in a file.

ast.copy_location(*new_node*, *old_node*)

Copy source location (**lineno**, **col_offset**, **end_lineno**, and **end_col_offset**) from *old_node* to *new_node* if possible, and return *new_node*.

ast.iter_fields(*node*)

Yield a tuple of `(fieldname, value)` for each field in `node._fields` that is present on *node*.

ast.iter_child_nodes(*node*)

Yield all direct child nodes of *node*, that is, all fields that are nodes and all items of fields that are lists of nodes.

ast.walk(*node*)

Recursively yield all descendant nodes in the tree starting at *node* (including *node* itself), in no specified order. This is useful if you only want to modify nodes in place and don't care about the context.

class ast.NodeVisitor

A node visitor base class that walks the abstract syntax tree and calls a visitor function for every node found. This

function may return a value which is forwarded by the **`visit()`** method.

This class is meant to be subclassed, with the subclass adding visitor methods.

visit(*node*)

Visit a node. The default implementation calls the method called `self.visit_`*classname* where *classname* is the name of the node class, or **`generic_visit()`** if that method doesn't exist.

generic_visit(*node*)

This visitor calls **`visit()`** on all children of the node.

Note that child nodes of nodes that have a custom visitor method won't be visited unless the visitor calls **`generic_visit()`** or visits them itself.

Don't use the **`NodeVisitor`** if you want to apply changes to nodes during traversal. For this a special visitor exists (**`NodeTransformer`**) that allows modifications.

Deprecated since version 3.8: Methods **`visit_Num()`**, **`visit_Str()`**, **`visit_Bytes()`**, **`visit_NameConstant()`** and **`visit_Ellipsis()`** are deprecated now and will not be called in future Python versions. Add the **`visit_Constant()`** method to handle all constant nodes.

class ast.NodeTransformer

A **`NodeVisitor`** subclass that walks the abstract syntax tree and allows modification of nodes.

The **`NodeTransformer`** will walk the AST and use the return value of the visitor methods to replace or remove the old node. If the return value of the visitor method is `None`, the node will be removed from its location, otherwise it is replaced with the return value. The return value may be the

original node in which case no replacement takes place.

Here is an example transformer that rewrites all occurrences of name lookups (`foo`) to `data['foo']`:

```
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Constant(value=node.id),
            ctx=node.ctx
        )
```

Keep in mind that if the node you're operating on has child nodes you must either transform the child nodes yourself or call the **`generic_visit()`** method for the node first.

For nodes that were part of a collection of statements (that applies to all statement nodes), the visitor may also return a list of nodes rather than just a single node.

If **`NodeTransformer`** introduces new nodes (that weren't part of original tree) without giving them location information (such as **`lineno`**), **`fix_missing_locations()`** should be called with the new sub-tree to recalculate the location information:

```
tree = ast.parse('foo', mode='eval')
new_tree = fix_missing_locations(RewriteName().visi
```

Usually you use the transformer like this:

```
node = YourTransformer().visit(node)
```

ast.dump(*node*, *annotate_fields=True*, *include_attributes=False*, ***, *indent=None*)

Return a formatted dump of the tree in *node*. This is mainly useful for debugging purposes. If *annotate_fields* is true (by default), the returned string will show the names and the

values for fields. If *annotate_fields* is false, the result string will be more compact by omitting unambiguous field names. Attributes such as line numbers and column offsets are not dumped by default. If this is wanted, *include_attributes* can be set to true.

If *indent* is a non-negative integer or string, then the tree will be pretty-printed with that indent level. An indent level of 0, negative, or `""` will only insert newlines. `None` (the default) selects the single line representation. Using a positive integer indent indents that many spaces per level. If *indent* is a string (such as `"\t"`), that string is used to indent each level.

Changed in version 3.9: Added the *indent* option.

Compiler Flags

The following flags may be passed to **`compile()`** in order to change effects on the compilation of a program:

ast.PyCF_ALLOW_TOP_LEVEL_AWAIT

Enables support for top-level `await`, `async for`, `async with` and async comprehensions.

New in version 3.8.

ast.PyCF_ONLY_AST

Generates and returns an abstract syntax tree instead of returning a compiled code object.

ast.PyCF_TYPE_COMMENTS

Enables support for **PEP 484** [https://peps.python.org/pep-0484/] and **PEP 526** [https://peps.python.org/pep-0526/] style type comments (`# type: <type>`, `# type: ignore <stuff>`).

New in version 3.8.

Command-Line Usage

New in version 3.9.

The **ast** module can be executed as a script from the command line. It is as simple as:

```
python -m ast [-m <mode>] [-a] [infile]
```

The following options are accepted:

-h, --help
: Show the help message and exit.

-m <mode>
--mode <mode>
: Specify what kind of code must be compiled, like the *mode* argument in **parse()**.

--no-type-comments
: Don't parse type comments.

-a, --include-attributes
: Include attributes such as line numbers and column offsets.

-i <indent>
--indent <indent>
: Indentation of nodes in AST (number of spaces).

If `infile` is specified its contents are parsed to AST and dumped to stdout. Otherwise, the content is read from stdin.

Green Tree Snakes [https://greentreesnakes.readthedocs.io/], an external documentation resource, has good details on working with Python ASTs.

ASTTokens [https://asttokens.readthedocs.io/en/latest/user-guide.html] annotates Python ASTs with the positions of tokens and text in the source code that generated them. This is helpful for tools that

make source code transformations.

leoAst.py [https://leoeditor.com/appendices.html#leoast-py] unifies the token-based and parse-tree-based views of python programs by inserting two-way links between tokens and ast nodes.

LibCST [https://libcst.readthedocs.io/] parses code as a Concrete Syntax Tree that looks like an ast tree and keeps all formatting details. It's useful for building automated refactoring (codemod) applications and linters.

Parso [https://parso.readthedocs.io] is a Python parser that supports error recovery and round-trip parsing for different Python versions (in multiple Python versions). Parso is also able to list multiple syntax errors in your python file.

`symtable` — Access to the compiler's symbol tables

Source code: Lib/symtable.py [https://github.com/python/cpython/tree/3.11/Lib/symtable.py]

Symbol tables are generated by the compiler from AST just before bytecode is generated. The symbol table is responsible for calculating the scope of every identifier in the code. `symtable` provides an interface to examine these tables.

Generating Symbol Tables

symtable.symtable(*code*, *filename*, *compile_type*)

Return the toplevel `SymbolTable` for the Python source *code*. *filename* is the name of the file containing the code. *compile_type* is like the *mode* argument to `compile()`.

Examining Symbol Tables

class symtable.SymbolTable

A namespace table for a block. The constructor is not public.

get_type()

Return the type of the symbol table. Possible values are `'class'`, `'module'`, and `'function'`.

get_id()

Return the table's identifier.

get_name()

Return the table's name. This is the name of the class if the table is for a class, the name of the function if the table is for a function, or `'top'` if the table is global (**`get_type()`** returns `'module'`).

get_lineno()

Return the number of the first line in the block this table represents.

is_optimized()

Return `True` if the locals in this table can be optimized.

is_nested()

Return `True` if the block is a nested class or function.

has_children()

Return `True` if the block has nested namespaces within it. These can be obtained with **`get_children()`**.

get_identifiers()

Return a view object containing the names of symbols in the table. See the documentation of view objects.

lookup(*name*)

Lookup *name* in the table and return a **`Symbol`** instance.

get_symbols()

Return a list of **`Symbol`** instances for names in the table.

get_children()

Return a list of the nested symbol tables.

class symtable.Function

A namespace for a function or method. This class inherits **SymbolTable**.

get_parameters()

Return a tuple containing names of parameters to this function.

get_locals()

Return a tuple containing names of locals in this function.

get_globals()

Return a tuple containing names of globals in this function.

get_nonlocals()

Return a tuple containing names of nonlocals in this function.

get_frees()

Return a tuple containing names of free variables in this function.

class symtable.Class

A namespace of a class. This class inherits **SymbolTable**.

get_methods()

Return a tuple containing the names of methods declared in the class.

class symtable.Symbol

An entry in a **SymbolTable** corresponding to an identifier in the source. The constructor is not public.

get_name()

Return the symbol's name.

is_referenced()

Return `True` if the symbol is used in its block.

is_imported()

Return `True` if the symbol is created from an import statement.

is_parameter()

Return `True` if the symbol is a parameter.

is_global()

Return `True` if the symbol is global.

is_nonlocal()

Return `True` if the symbol is nonlocal.

is_declared_global()

Return `True` if the symbol is declared global with a global statement.

is_local()

Return `True` if the symbol is local to its block.

is_annotated()

Return `True` if the symbol is annotated.

New in version 3.6.

is_free()

Return `True` if the symbol is referenced in its block, but not assigned to.

is_assigned()

Return `True` if the symbol is assigned to in its block.

is_namespace()

Return `True` if name binding introduces new namespace.

If the name is used as the target of a function or class statement, this will be true.

For example:

```
>>> table = symtable.symtable("def some_func():
>>> table.lookup("some_func").is_namespace()
True
```

Note that a single name can be bound to multiple objects. If the result is `True`, the name may also be bound to other objects, like an int or list, that does not introduce a new namespace.

get_namespaces()

Return a list of namespaces bound to this name.

get_namespace()

Return the namespace bound to this name. If more than one or no namespace is bound to this name, a **`ValueError`** is raised.

`token` — Constants used with Python parse trees

Source code: Lib/token.py [https://github.com/python/cpython/tree/3.11/Lib/token.py]

This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file `Grammar/Tokens` in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

The module also provides a mapping from numeric codes to names and some functions. The functions mirror definitions in the Python C header files.

token.tok_name

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

token.ISTERMINAL(*x*)

Return `True` for terminal token values.

token.ISNONTERMINAL(*x*)

Return `True` for non-terminal token values.

token.ISEOF(*x*)

Return `True` if *x* is the marker indicating the end of input.

The token constants are:

token.ENDMARKER

token.NAME

token.NUMBER

token.STRING

token.NEWLINE

token.INDENT

token.DEDENT

token.LPAR
: Token value for `"("`.

token.RPAR
: Token value for `")"`.

token.LSQB
: Token value for `"["`.

token.RSQB
: Token value for `"]"`.

token.COLON
: Token value for `":"`.

token.COMMA
: Token value for `","`.

token.SEMI
: Token value for `";"`.

token.PLUS

Token value for "+".

token.MINUS
Token value for "-".

token.STAR
Token value for "*".

token.SLASH
Token value for "/".

token.VBAR
Token value for "|".

token.AMPER
Token value for "&".

token.LESS
Token value for "<".

token.GREATER
Token value for ">".

token.EQUAL
Token value for "=".

token.DOT
Token value for ".".

token.PERCENT
Token value for "%".

token.LBRACE
Token value for "{".

token.RBRACE

Token value for "}".

token.EQEQUAL
Token value for "==".

token.NOTEQUAL
Token value for "!=".

token.LESSEQUAL
Token value for "<=".

token.GREATEREQUAL
Token value for ">=".

token.TILDE
Token value for "~".

token.CIRCUMFLEX
Token value for "^".

token.LEFTSHIFT
Token value for "<<".

token.RIGHTSHIFT
Token value for ">>".

token.DOUBLESTAR
Token value for "**".

token.PLUSEQUAL
Token value for "+=".

token.MINEQUAL
Token value for "-=".

token.STAREQUAL

Token value for "*=".

token.SLASHEQUAL
Token value for "/=".

token.PERCENTEQUAL
Token value for "%=".

token.AMPEREQUAL
Token value for "&=".

token.VBAREQUAL
Token value for "|=".

token.CIRCUMFLEXEQUAL
Token value for "^=".

token.LEFTSHIFTEQUAL
Token value for "<<=".

token.RIGHTSHIFTEQUAL
Token value for ">>=".

token.DOUBLESTAREQUAL
Token value for "**=".

token.DOUBLESLASH
Token value for "//".

token.DOUBLESLASHEQUAL
Token value for "//=".

token.AT
Token value for "@".

token.ATEQUAL

Token value for `"@="`.

token.RARROW
: Token value for `"->"`.

token.ELLIPSIS
: Token value for `"..."`.

token.COLONEQUAL
: Token value for `":="`.

token.OP

token.AWAIT

token.ASYNC

token.TYPE_IGNORE

token.TYPE_COMMENT

token.SOFT_KEYWORD

token.ERRORTOKEN

token.N_TOKENS

token.NT_OFFSET

The following token type values aren't used by the C tokenizer but are needed for the **`tokenize`** module.

token.COMMENT
: Token value used to indicate a comment.

token.NL
: Token value used to indicate a non-terminating newline. The

NEWLINE token indicates the end of a logical line of Python code; `NL` tokens are generated when a logical line of code is continued over multiple physical lines.

token.ENCODING

Token value that indicates the encoding used to decode the source bytes into text. The first token returned by **tokenize.tokenize()** will always be an `ENCODING` token.

token.TYPE_COMMENT

Token value indicating that a type comment was recognized. Such tokens are only produced when **ast.parse()** is invoked with `type_comments=True`.

Changed in version 3.5: Added **AWAIT** and **ASYNC** tokens.

Changed in version 3.7: Added **COMMENT**, **NL** and **ENCODING** tokens.

Changed in version 3.7: Removed **AWAIT** and **ASYNC** tokens. “async” and “await” are now tokenized as **NAME** tokens.

Changed in version 3.8: Added **TYPE_COMMENT**, **TYPE_IGNORE**, **COLONEQUAL**. Added **AWAIT** and **ASYNC** tokens back (they’re needed to support parsing older Python versions for **ast.parse()** with `feature_version` set to 6 or lower).

`keyword` — Testing for Python keywords

Source code: Lib/keyword.py [https://github.com/python/cpython/tree/3.11/Lib/keyword.py]

This module allows a Python program to determine if a string is a keyword or soft keyword.

keyword.iskeyword(*s*)

Return `True` if *s* is a Python keyword.

keyword.kwlist

Sequence containing all the keywords defined for the interpreter. If any keywords are defined to only be active when particular `__future__` statements are in effect, these will be included as well.

keyword.issoftkeyword(*s*)

Return `True` if *s* is a Python soft keyword.

New in version 3.9.

keyword.softkwlist

Sequence containing all the soft keywords defined for the interpreter. If any soft keywords are defined to only be active when particular `__future__` statements are in effect, these will be included as well.

New in version 3.9.

`tokenize` — Tokenizer for Python source

Source code: Lib/tokenize.py [https://github.com/python/cpython/tree/3.11/Lib/tokenize.py]

The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing "pretty-printers", including colorizers for on-screen displays.

To simplify token stream handling, all operator and delimiter tokens and `Ellipsis` are returned using the generic `OP` token type. The exact type can be determined by checking the `exact_type` property on the named tuple returned from `tokenize.tokenize()`.

Tokenizing Input

The primary entry point is a generator:

tokenize.tokenize(*readline*)

> The `tokenize()` generator requires one argument, *readline*, which must be a callable object which provides the same interface as the `io.IOBase.readline()` method of file objects. Each call to the function should return one line of input as bytes.
>
> The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple `(srow, scol)` of ints specifying the row and column where the token begins in the source; a 2-tuple `(erow, ecol)` of ints specifying the row and column where the token ends in the source; and the line

on which the token was found. The line passed (the last tuple item) is the *physical* line. The 5 tuple is returned as a named tuple with the field names: `type string start end line`.

The returned named tuple has an additional property named `exact_type` that contains the exact operator type for **`OP`** tokens. For all other token types `exact_type` equals the named tuple `type` field.

Changed in version 3.1: Added support for named tuples.

Changed in version 3.3: Added support for `exact_type`.

`tokenize()` determines the source encoding of the file by looking for a UTF-8 BOM or encoding cookie, according to **PEP 263** [https://peps.python.org/pep-0263/].

tokenize.generate_tokens(*readline*)

Tokenize a source reading unicode strings instead of bytes.

Like **`tokenize()`**, the *readline* argument is a callable returning a single line of input. However, **`generate_tokens()`** expects *readline* to return a str object rather than bytes.

The result is an iterator yielding named tuples, exactly like **`tokenize()`**. It does not yield an **`ENCODING`** token.

All constants from the **`token`** module are also exported from **`tokenize`**.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

tokenize.untokenize(*iterable*)

Converts tokens back into Python source code. The *iterable* must return sequences with at least two elements, the token type and the token string. Any additional sequence elements

are ignored.

The reconstructed script is returned as a single string. The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

It returns bytes, encoded using the **ENCODING** token, which is the first token sequence output by **tokenize()**. If there is no encoding token in the input, it returns a str instead.

tokenize() needs to detect the encoding of source files it tokenizes. The function it uses to do this is available:

tokenize.detect_encoding(*readline*)

The **detect_encoding()** function is used to detect the encoding that should be used to decode a Python source file. It requires one argument, readline, in the same way as the **tokenize()** generator.

It will call readline a maximum of twice, and return the encoding used (as a string) and a list of any lines (not decoded from bytes) it has read in.

It detects the encoding from the presence of a UTF-8 BOM or an encoding cookie as specified in **PEP 263** [https://peps.python.org/pep-0263/]. If both a BOM and a cookie are present, but disagree, a **SyntaxError** will be raised. Note that if the BOM is found, `'utf-8-sig'` will be returned as an encoding.

If no encoding is specified, then the default of `'utf-8'` will be returned.

Use **open()** to open Python source files: it uses **detect_encoding()** to detect the file encoding.

tokenize.open(*filename*)

Open a file in read only mode using the encoding detected by **detect_encoding()**.

New in version 3.2.

exception tokenize.TokenError

Raised when either a docstring or expression that may be split over several lines is not completed anywhere in the file, for example:

```
"""Beginning of
docstring
```

or:

```
[1,
 2,
 3
```

Note that unclosed single-quoted strings do not cause an error to be raised. They are tokenized as **ERRORTOKEN**, followed by the tokenization of their contents.

Command-Line Usage

New in version 3.3.

The **tokenize** module can be executed as a script from the command line. It is as simple as:

```
python -m tokenize [-e] [filename.py]
```

The following options are accepted:

-h, --help

show this help message and exit

-e, --exact

display token names using the exact type

If `filename.py` is specified its contents are tokenized to stdout. Otherwise, tokenization is performed on stdin.

Examples

Example of a script rewriter that transforms float literals into Decimal objects:

```
from tokenize import tokenize, untokenize, NUMBER, STRIN
from io import BytesIO

def decistmt(s):
    """Substitute Decimals for floats in a string of sta

    >>> from decimal import Decimal
    >>> s = 'print(+21.3e-5*-.1234/81.7)'
    >>> decistmt(s)
    "print (+Decimal ('21.3e-5')*-Decimal ('.1234')/Deci

    The format of the exponent is inherited from the pla
    Known cases are "e-007" (Windows) and "e-07" (not Wi
    we're only showing 12 digits, and the 13th isn't clo
    rest of the output should be platform-independent.

    >>> exec(s)  #doctest: +ELLIPSIS
    -3.21716034272e-0...7

    Output from calculations with Decimal should be iden
    platforms.

    >>> exec(decistmt(s))
    -3.217160342717258261933904529E-7
    """
    result = []
    g = tokenize(BytesIO(s.encode('utf-8')).readline)  #
    for toknum, tokval, _, _, _ in g:
        if toknum == NUMBER and '.' in tokval:  # replac
            result.extend([
```

```
                (NAME, 'Decimal'),
                (OP, '('),
                (STRING, repr(tokval)),
                (OP, ')')
            ])
        else:
            result.append((toknum, tokval))
    return untokenize(result).decode('utf-8')
```

Example of tokenizing from the command line. The script:

```
def say_hello():
    print("Hello, World!")

say_hello()
```

will be tokenized to the following output where the first column is the range of the line/column coordinates where the token is found, the second column is the name of the token, and the final column is the value of the token (if any)

```
$ python -m tokenize hello.py
0,0-0,0:            ENCODING       'utf-8'
1,0-1,3:            NAME           'def'
1,4-1,13:           NAME           'say_hello'
1,13-1,14:          OP             '('
1,14-1,15:          OP             ')'
1,15-1,16:          OP             ':'
1,16-1,17:          NEWLINE        '\n'
2,0-2,4:            INDENT         '    '
2,4-2,9:            NAME           'print'
2,9-2,10:           OP             '('
2,10-2,25:          STRING         '"Hello, World!"'
2,25-2,26:          OP             ')'
2,26-2,27:          NEWLINE        '\n'
3,0-3,1:            NL             '\n'
4,0-4,0:            DEDENT         ''
4,0-4,9:            NAME           'say_hello'
4,9-4,10:           OP             '('
```

```
4,10-4,11:            OP              ')'
4,11-4,12:            NEWLINE         '\n'
5,0-5,0:              ENDMARKER       ''
```

The exact token type names can be displayed using the **`-e`** option:

```
$ python -m tokenize -e hello.py
0,0-0,0:              ENCODING        'utf-8'
1,0-1,3:              NAME            'def'
1,4-1,13:             NAME            'say_hello'
1,13-1,14:            LPAR            '('
1,14-1,15:            RPAR            ')'
1,15-1,16:            COLON           ':'
1,16-1,17:            NEWLINE         '\n'
2,0-2,4:              INDENT          '    '
2,4-2,9:              NAME            'print'
2,9-2,10:             LPAR            '('
2,10-2,25:            STRING          '"Hello, World!"'
2,25-2,26:            RPAR            ')'
2,26-2,27:            NEWLINE         '\n'
3,0-3,1:              NL              '\n'
4,0-4,0:              DEDENT          ''
4,0-4,9:              NAME            'say_hello'
4,9-4,10:             LPAR            '('
4,10-4,11:            RPAR            ')'
4,11-4,12:            NEWLINE         '\n'
5,0-5,0:              ENDMARKER       ''
```

Example of tokenizing a file programmatically, reading unicode strings instead of bytes with **`generate_tokens()`**:

```
import tokenize

with tokenize.open('hello.py') as f:
    tokens = tokenize.generate_tokens(f.readline)
    for token in tokens:
        print(token)
```

Or reading bytes directly with **`tokenize()`**:

```
import tokenize

with open('hello.py', 'rb') as f:
    tokens = tokenize.tokenize(f.readline)
    for token in tokens:
        print(token)
```

`tabnanny` — Detection of ambiguous indentation

Source code: Lib/tabnanny.py [https://github.com/python/cpython/tree/3.11/Lib/tabnanny.py]

For the time being this module is intended to be called as a script. However it is possible to import it into an IDE and use the function `check()` described below.

Note

The API provided by this module is likely to change in future releases; such changes may not be backward compatible.

tabnanny.check(*file_or_dir*)

If *file_or_dir* is a directory and not a symbolic link, then recursively descend the directory tree named by *file_or_dir*, checking all `.py` files along the way. If *file_or_dir* is an ordinary Python source file, it is checked for whitespace related problems. The diagnostic messages are written to standard output using the `print()` function.

tabnanny.verbose

Flag indicating whether to print verbose messages. This is incremented by the `-v` option if called as a script.

tabnanny.filename_only

Flag indicating whether to print only the filenames of files containing whitespace related problems. This is set to true by the `-q` option if called as a script.

exception tabnanny.NannyNag

Raised by `process_tokens()` if detecting an ambiguous indent. Captured and handled in `check()`.

tabnanny.process_tokens(*tokens*)

This function is used by `check()` to process tokens generated by the `tokenize` module.

Module `tokenize`
Lexical scanner for Python source code.

`pyclbr` — Python module browser support

Source code: Lib/pyclbr.py [https://github.com/python/cpython/tree/3.11/Lib/pyclbr.py]

The `pyclbr` module provides limited information about the functions, classes, and methods defined in a Python-coded module. The information is sufficient to implement a module browser. The information is extracted from the Python source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

pyclbr.readmodule(*module*, *path*=*None*)

Return a dictionary mapping module-level class names to class descriptors. If possible, descriptors for imported base classes are included. Parameter *module* is a string with the name of the module to read; it may be the name of a module within a package. If given, *path* is a sequence of directory paths prepended to `sys.path`, which is used to locate the module source code.

This function is the original interface and is only kept for back compatibility. It returns a filtered version of the following.

pyclbr.readmodule_ex(*module*, *path*=*None*)

Return a dictionary-based tree containing a function or class descriptors for each function and class defined in the module with a `def` or `class` statement. The returned dictionary maps module-level function and class names to their descriptors. Nested objects are entered into the children

dictionary of their parent. As with readmodule, *module* names the module to be read and *path* is prepended to sys.path. If the module being read is a package, the returned dictionary has a key `'__path__'` whose value is a list containing the package search path.

New in version 3.7: Descriptors for nested definitions. They are accessed through the new children attribute. Each has a new parent attribute.

The descriptors returned by these functions are instances of Function and Class classes. Users are not expected to create instances of these classes.

Function Objects

Class **`Function`** instances describe functions defined by def statements. They have the following attributes:

Function.file

Name of the file in which the function is defined.

Function.module

The name of the module defining the function described.

Function.name

The name of the function.

Function.lineno

The line number in the file where the definition starts.

Function.parent

For top-level functions, None. For nested functions, the parent.

New in version 3.7.

Function.children

A dictionary mapping names to descriptors for nested functions and classes.

New in version 3.7.

Function.is_async

`True` for functions that are defined with the `async` prefix, `False` otherwise.

New in version 3.10.

Class Objects

Class **`Class`** instances describe classes defined by class statements. They have the same attributes as Functions and two more.

Class.file

Name of the file in which the class is defined.

Class.module

The name of the module defining the class described.

Class.name

The name of the class.

Class.lineno

The line number in the file where the definition starts.

Class.parent

For top-level classes, None. For nested classes, the parent.

New in version 3.7.

Class.children

A dictionary mapping names to descriptors for nested functions and classes.

New in version 3.7.

Class.super

A list of **`Class`** objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by **`readmodule_ex()`** are listed as a string with the class name instead of as **`Class`** objects.

Class.methods

A dictionary mapping method names to line numbers. This can be derived from the newer children dictionary, but remains for back-compatibility.

py_compile — Compile Python source files

Source code: Lib/py_compile.py [https://github.com/python/cpython/tree/3.11/Lib/py_compile.py]

The py_compile module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

exception py_compile.PyCompileError

Exception raised when an error occurs while attempting to compile the file.

py_compile.compile(*file*, *cfile=None*, *dfile=None*, *doraise=False*, *optimize=-1*, *invalidation_mode=PycInvalidationMode.TIMESTAMP*, *quiet=0*)

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file named *file*. The byte-code is written to *cfile*, which defaults to the PEP 3147 [https://peps.python.org/pep-3147/]/PEP 488 [https://peps.python.org/pep-0488/] path, ending in `.pyc`. For example, if *file* is `/foo/bar/baz.py` *cfile* will default to `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. If *dfile* is specified, it is used instead of *file* as the name of the source file from which source lines are obtained for display in exception tracebacks. If *doraise* is true, a PyCompileError is raised when an error is encountered while compiling *file*. If *doraise* is false (the default), an error string is written to

`sys.stderr`, but no exception is raised. This function returns the path to byte-compiled file, i.e. whatever *cfile* value was used.

The *doraise* and *quiet* arguments determine how errors are handled while compiling file. If *quiet* is 0 or 1, and *doraise* is false, the default behaviour is enabled: an error string is written to `sys.stderr`, and the function returns `None` instead of a path. If *doraise* is true, a **`PyCompileError`** is raised instead. However if *quiet* is 2, no message is written, and *doraise* has no effect.

If the path that *cfile* becomes (either explicitly specified or computed) is a symlink or non-regular file, **`FileExistsError`** will be raised. This is to act as a warning that import will turn those paths into regular files if it is allowed to write byte-compiled files to those paths. This is a side-effect of import using file renaming to place the final byte-compiled file into place to prevent concurrent file writing issues.

optimize controls the optimization level and is passed to the built-in **`compile()`** function. The default of `-1` selects the optimization level of the current interpreter.

invalidation_mode should be a member of the **`PycInvalidationMode`** enum and controls how the generated bytecode cache is invalidated at runtime. The default is **`PycInvalidationMode.CHECKED_HASH`** if the **`SOURCE_DATE_EPOCH`** environment variable is set, otherwise the default is **`PycInvalidationMode.TIMESTAMP`**.

Changed in version 3.2: Changed default value of *cfile* to be **PEP 3147** [https://peps.python.org/pep-3147/]-compliant. Previous default was *file* + `'c'` (`'o'` if optimization was enabled). Also added the *optimize* parameter.

Changed in version 3.4: Changed code to use **`importlib`** for the byte-code cache file writing. This means file creation/ writing semantics now match what **`importlib`** does, e.g. permissions, write-and-move semantics, etc. Also added the

caveat that **FileExistsError** is raised if *cfile* is a symlink or non-regular file.

Changed in version 3.7: The *invalidation_mode* parameter was added as specified in **PEP 552** [https://peps.python.org/pep-0552/]. If the **SOURCE_DATE_EPOCH** environment variable is set, *invalidation_mode* will be forced to **PycInvalidationMode.CHECKED_HASH**.

Changed in version 3.7.2: The **SOURCE_DATE_EPOCH** environment variable no longer overrides the value of the *invalidation_mode* argument, and determines its default value instead.

Changed in version 3.8: The *quiet* parameter was added.

class py_compile.PycInvalidationMode

A enumeration of possible methods the interpreter can use to determine whether a bytecode file is up to date with a source file. The `.pyc` file indicates the desired invalidation mode in its header. See Cached bytecode invalidation for more information on how Python invalidates `.pyc` files at runtime.

New in version 3.7.

TIMESTAMP

The `.pyc` file includes the timestamp and size of the source file, which Python will compare against the metadata of the source file at runtime to determine if the `.pyc` file needs to be regenerated.

CHECKED_HASH

The `.pyc` file includes a hash of the source file content, which Python will compare against the source at runtime to determine if the `.pyc` file needs to be regenerated.

UNCHECKED_HASH

Like **CHECKED_HASH**, the `.pyc` file includes a hash of the source file content. However, Python will at runtime assume the `.pyc` file is up to date and not validate the `.pyc` against the source file at all.

This option is useful when the `.pycs` are kept up to date by some system external to Python like a build system.

Command-Line Interface

This module can be invoked as a script to compile several source files. The files named in *filenames* are compiled and the resulting bytecode is cached in the normal manner. This program does not search a directory structure to locate source files; it only compiles files named explicitly. The exit status is nonzero if one of the files could not be compiled.

<file> ... <fileN>
-

Positional arguments are files to compile. If `-` is the only parameter, the list of files is taken from standard input.

-q, --quiet

Suppress errors output.

Changed in version 3.2: Added support for `-`.

Changed in version 3.10: Added support for **-q**.

See also

Module **compileall**

Utilities to compile all Python source files in a directory tree.

`compileall` — Byte-compile Python libraries

Source code: Lib/compileall.py [https://github.com/python/cpython/tree/3.11/Lib/compileall.py]

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached byte-code files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Command-line use

This module can work as a script (using **python -m compileall**) to compile Python sources.

directory ...
file ...

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

-l

Do not recurse into subdirectories, only compile source code

files directly contained in the named or implied directories.

-f

Force rebuild even if timestamps are up-to-date.

-q

Do not print the list of files compiled. If passed once, error messages will still be printed. If passed twice (`-qq`), all output is suppressed.

-d destdir

Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

-s strip_prefix

-p prepend_prefix

Remove (`-s`) or append (`-p`) the given prefix of paths recorded in the `.pyc` files. Cannot be combined with `-d`.

-x regex

regex is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.

-i list

Read the file `list` and add each line that it contains to the list of files and directories to compile. If `list` is `-`, read lines from `stdin`.

-b

Write the byte-code files to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their **PEP**

3147 [https://peps.python.org/pep-3147/] locations and names, which allows byte-code files from multiple versions of Python to coexist.

-r

Control the maximum recursion level for subdirectories. If this is given, then `-l` option will not be taken into account. **python -m compileall <directory> -r 0** is equivalent to **python -m compileall <directory> -l**.

-j N

Use *N* workers to compile the files within the given directory. If `0` is used, then the result of **`os.cpu_count()`** will be used.

--invalidation-mode [timestamp|checked-hash|unchecked-hash]

Control how the generated byte-code files are invalidated at runtime. The `timestamp` value, means that `.pyc` files with the source timestamp and size embedded will be generated. The `checked-hash` and `unchecked-hash` values cause hash-based pycs to be generated. Hash-based pycs embed a hash of the source file contents rather than a timestamp. See Cached bytecode invalidation for more information on how Python validates bytecode cache files at runtime. The default is `timestamp` if the **`SOURCE_DATE_EPOCH`** environment variable is not set, and `checked-hash` if the `SOURCE_DATE_EPOCH` environment variable is set.

-o level

Compile with the given optimization level. May be used multiple times to compile for multiple levels at a time (for example, `compileall -o 1 -o 2`).

-e dir

Ignore symlinks pointing outside the given directory.

--hardlink-dupes

If two `.pyc` files with different optimization level have the

same content, use hard links to consolidate duplicate files.

Changed in version 3.2: Added the `-i`, `-b` and `-h` options.

Changed in version 3.5: Added the `-j`, `-r`, and `-qq` options. `-q` option was changed to a multilevel value. `-b` will always produce a byte-code file ending in `.pyc`, never `.pyo`.

Changed in version 3.7: Added the `--invalidation-mode` option.

Changed in version 3.9: Added the `-s`, `-p`, `-e` and `--hardlink-dupes` options. Raised the default recursion limit from 10 to **`sys.getrecursionlimit()`**. Added the possibility to specify the `-o` option multiple times.

There is no command-line option to control the optimization level used by the **`compile()`** function, because the Python interpreter itself already provides the option: **python -O -m compileall**.

Similarly, the **`compile()`** function respects the **`sys.pycache_prefix`** setting. The generated bytecode cache will only be useful if **`compile()`** is run with the same **`sys.pycache_prefix`** (if any) that will be used at runtime.

Public functions

compileall.compile_dir(*dir*, *maxlevels=sys.getrecursionlimit()*, *ddir=None*, *force=False*, *rx=None*, *quiet=0*, *legacy=False*, *optimize=-1*, *workers=1*, *invalidation_mode=None*, ***, *stripdir=None*, *prependdir=None*, *limit_sl_dest=None*, *hardlink_dupes=False*)

Recursively descend the directory tree named by *dir*, compiling all `.py` files along the way. Return a true value if all the files compiled successfully, and a false value otherwise.

The *maxlevels* parameter is used to limit the depth of the recursion; it defaults to `sys.getrecursionlimit()`.

If *ddir* is given, it is prepended to the path to each file being

compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *force* is true, modules are re-compiled even if the timestamps are up to date.

If *rx* is given, its `search` method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped. This can be used to exclude files matching a regular expression, given as a re.Pattern object.

If *quiet* is `False` or `0` (the default), the filenames and other information are printed to standard out. Set to `1`, only errors are printed. Set to `2`, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their **PEP 3147** [https://peps.python.org/pep-3147/] locations and names, which allows byte-code files from multiple versions of Python to coexist.

optimize specifies the optimization level for the compiler. It is passed to the built-in **`compile()`** function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

The argument *workers* specifies how many workers are used to compile files in parallel. The default is to not use multiple workers. If the platform can't use multiple workers and *workers* argument is given, then sequential compilation will be used as a fallback. If *workers* is 0, the number of cores in the system is used. If *workers* is lower than `0`, a **`ValueError`** will be raised.

invalidation_mode should be a member of the **`py_compile.PycInvalidationMode`** enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit_sl_dest* arguments correspond to the `-s`, `-p` and `-e` options described above. They may be specified as `str`, `bytes` or **`os.PathLike`**.

If *hardlink_dupes* is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

Changed in version 3.2: Added the *legacy* and *optimize* parameter.

Changed in version 3.5: Added the *workers* parameter.

Changed in version 3.5: *quiet* parameter was changed to a multilevel value.

Changed in version 3.5: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

Changed in version 3.6: Accepts a path-like object.

Changed in version 3.7: The *invalidation_mode* parameter was added.

Changed in version 3.7.2: The *invalidation_mode* parameter's default value is updated to None.

Changed in version 3.8: Setting *workers* to 0 now chooses the optimal number of cores.

Changed in version 3.9: Added *stripdir*, *prependdir*, *limit_sl_dest* and *hardlink_dupes* arguments. Default value of *maxlevels* was changed from `10` to `sys.getrecursionlimit()`

compileall.compile_file(*fullname*, *ddir=None*, *force=False*, *rx=None*, *quiet=0*, *legacy=False*, *optimize=-1*, *invalidation_mode=None*, ***, *stripdir=None*, *prependdir=None*, *limit_sl_dest=None*, *hardlink_dupes=False*)

Compile the file with path *fullname*. Return a true value if the file compiled successfully, and a false value otherwise.

If *ddir* is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *rx* is given, its `search` method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and `True` is returned. This can be used to exclude files matching a regular expression, given as a re.Pattern object.

If *quiet* is `False` or `0` (the default), the filenames and other information are printed to standard out. Set to `1`, only errors are printed. Set to `2`, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their **PEP 3147** [https://peps.python.org/pep-3147/] locations and names, which allows byte-code files from multiple versions of Python to coexist.

optimize specifies the optimization level for the compiler. It is passed to the built-in **`compile()`** function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

invalidation_mode should be a member of the **`py_compile.PycInvalidationMode`** enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit_sl_dest* arguments correspond to the `-s`, `-p` and `-e` options described above. They may be specified as `str`, `bytes` or **`os.PathLike`**.

If *hardlink_dupes* is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

New in version 3.2.

Changed in version 3.5: quiet parameter was changed to a multilevel value.

Changed in version 3.5: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

Changed in version 3.7: The *invalidation_mode* parameter was added.

Changed in version 3.7.2: The *invalidation_mode* parameter's default value is updated to None.

Changed in version 3.9: Added *stripdir*, *prependdir*, *limit_sl_dest* and *hardlink_dupes* arguments.

compileall.compile_path(*skip_curdir=True*, *maxlevels=0*, *force=False*, *quiet=0*, *legacy=False*, *optimize=-1*, *invalidation_mode=None*)

Byte-compile all the `.py` files found along `sys.path`. Return a true value if all the files compiled successfully, and a false value otherwise.

If *skip_curdir* is true (the default), the current directory is not included in the search. All other parameters are passed to the **`compile_dir()`** function. Note that unlike the other compile functions, `maxlevels` defaults to `0`.

Changed in version 3.2: Added the *legacy* and *optimize* parameter.

Changed in version 3.5: quiet parameter was changed to a multilevel value.

Changed in version 3.5: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

Changed in version 3.7: The *invalidation_mode* parameter was added.

Changed in version 3.7.2: The *invalidation_mode* parameter's default value is updated to None.

To force a recompile of all the `.py` files in the `Lib/` subdirectory and all its subdirectories:

```
import compileall

compileall.compile_dir('Lib/', force=True)

# Perform same compilation, excluding files in .svn dire
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\\][.]s

# pathlib.Path objects can also be used.
import pathlib
compileall.compile_dir(pathlib.Path('Lib/'), force=True)
```

See also

Module **py_compile**
Byte-compile a single source file.

`dis` — Disassembler for Python bytecode

Source code: Lib/dis.py [https://github.com/python/cpython/tree/3.11/Lib/dis.py]

The `dis` module supports the analysis of CPython bytecode by disassembling it. The CPython bytecode which this module takes as an input is defined in the file `Include/opcode.h` and used by the compiler and the interpreter.

CPython implementation detail: Bytecode is an implementation detail of the CPython interpreter. No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

Changed in version 3.6: Use 2 bytes for each instruction. Previously the number of bytes varied by instruction.

Changed in version 3.10: The argument of jump, exception handling and loop instructions is now the instruction offset rather than the byte offset.

Changed in version 3.11: Some instructions are accompanied by one or more inline cache entries, which take the form of `CACHE` instructions. These instructions are hidden by default, but can be shown by passing `show_caches=True` to any `dis` utility. Furthermore, the interpreter now adapts the bytecode to specialize it for different runtime conditions. The adaptive bytecode can be shown by passing `adaptive=True`.

Example: Given the function `myfunc()`:

```
def myfunc(alist):
```

```
    return len(alist)
```

the following command can be used to display the disassembly of **myfunc()**:

```
>>> dis.dis(myfunc)
  2           0 RESUME                   0

  3           2 LOAD_GLOBAL              1 (NULL + len)
             14 LOAD_FAST                0 (alist)
             16 PRECALL                  1
             20 CALL                     1
             30 RETURN_VALUE
```

(The “2” is a line number).

Bytecode analysis

New in version 3.4.

The bytecode analysis API allows pieces of Python code to be wrapped in a **Bytecode** object that provides easy access to details of the compiled code.

class dis.Bytecode(*x*, *, *first_line=None*, *current_offset=None*, *show_caches=False*, *adaptive=False*)

Analyse the bytecode corresponding to a function, generator, asynchronous generator, coroutine, method, string of source code, or a code object (as returned by **compile()**).

This is a convenience wrapper around many of the functions listed below, most notably **get_instructions()**, as iterating over a **Bytecode** instance yields the bytecode operations as **Instruction** instances.

If *first_line* is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

If *current_offset* is not `None`, it refers to an instruction offset in the disassembled code. Setting this means **`dis()`** will display a "current instruction" marker against the specified opcode.

If *show_caches* is `True`, **`dis()`** will display inline cache entries used by the interpreter to specialize the bytecode.

If *adaptive* is `True`, **`dis()`** will display specialized bytecode that may be different from the original bytecode.

classmethod from_traceback(*tb*, ***, *show_caches=False*)

Construct a **`Bytecode`** instance from the given traceback, setting *current_offset* to the instruction responsible for the exception.

codeobj

The compiled code object.

first_line

The first source line of the code object (if available)

dis()

Return a formatted view of the bytecode operations (the same as printed by **`dis.dis()`**, but returned as a multi-line string).

info()

Return a formatted multi-line string with detailed information about the code object, like **`code_info()`**.

Changed in version 3.7: This can now handle coroutine and asynchronous generator objects.

Changed in version 3.11: Added the *show_caches* and *adaptive* parameters.

Example:

```
>>> bytecode = dis.Bytecode(myfunc)
>>> for instr in bytecode:
...     print(instr.opname)
...
RESUME
LOAD_GLOBAL
LOAD_FAST
PRECALL
CALL
RETURN_VALUE
```

Analysis functions

The **dis** module also defines the following analysis functions that convert the input directly to the desired output. They can be useful if only a single operation is being performed, so the intermediate analysis object isn't useful:

dis.code_info(*x*)

Return a formatted multi-line string with detailed code object information for the supplied function, generator, asynchronous generator, coroutine, method, source code string or code object.

Note that the exact contents of code info strings are highly implementation dependent and they may change arbitrarily across Python VMs or Python releases.

New in version 3.2.

Changed in version 3.7: This can now handle coroutine and asynchronous generator objects.

dis.show_code(*x*, *, *file*=*None*)

Print detailed code object information for the supplied function, method, source code string or code object to *file* (or `sys.stdout` if *file* is not specified).

This is a convenient shorthand for `print(code_info(x),`

`file=file)`, intended for interactive exploration at the interpreter prompt.

New in version 3.2.

Changed in version 3.4: Added *file* parameter.

dis.dis(*x=None*, *, *file=None*, *depth=None*, *show_caches=False*, *adaptive=False*)

Disassemble the *x* object. *x* can denote either a module, a class, a method, a function, a generator, an asynchronous generator, a coroutine, a code object, a string of source code or a byte sequence of raw bytecode. For a module, it disassembles all functions. For a class, it disassembles all methods (including class and static methods). For a code object or sequence of raw bytecode, it prints one line per bytecode instruction. It also recursively disassembles nested code objects (the code of comprehensions, generator expressions and nested functions, and the code used for building nested classes). Strings are first compiled to code objects with the **`compile()`** built-in function before being disassembled. If no object is provided, this function disassembles the last traceback.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

The maximal depth of recursion is limited by *depth* unless it is `None`. `depth=0` means no recursion.

If *show_caches* is `True`, this function will display inline cache entries used by the interpreter to specialize the bytecode.

If *adaptive* is `True`, this function will display specialized bytecode that may be different from the original bytecode.

Changed in version 3.4: Added *file* parameter.

Changed in version 3.7: Implemented recursive disassembling and added *depth* parameter.

Changed in version 3.7: This can now handle coroutine and asynchronous generator objects.

Changed in version 3.11: Added the *show_caches* and *adaptive* parameters.

dis.distb(*tb=None*, ***, *file=None*, *show_caches=False*, *adaptive=False*)

Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

Changed in version 3.4: Added *file* parameter.

Changed in version 3.11: Added the *show_caches* and *adaptive* parameters.

dis.disassemble(*code*, *lasti=-1*, ***, *file=None*, *show_caches=False*, *adaptive=False*)
dis.disco(*code*, *lasti=-1*, ***, *file=None*, *show_caches=False*, *adaptive=False*)

Disassemble a code object, indicating the last instruction if *lasti* was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->`,
3. a labelled instruction, indicated with `>>`,
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

Changed in version 3.4: Added *file* parameter.

Changed in version 3.11: Added the *show_caches* and *adaptive* parameters.

dis.get_instructions(*x*, *, *first_line=None*, *show_caches=False*, *adaptive=False*)

Return an iterator over the instructions in the supplied function, method, source code string or code object.

The iterator generates a series of **`Instruction`** named tuples giving the details of each operation in the supplied code.

If *first_line* is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

The *show_caches* and *adaptive* parameters work as they do in **`dis()`**.

New in version 3.4.

Changed in version 3.11: Added the *show_caches* and *adaptive* parameters.

dis.findlinestarts(*code*)

This generator function uses the `co_lines` method of the code object *code* to find the offsets which are starts of lines in the source code. They are generated as `(offset, lineno)` pairs.

Changed in version 3.6: Line numbers can be decreasing. Before, they were always increasing.

Changed in version 3.10: The **PEP 626** [https://peps.python.org/

pep-0626/] `co_lines` method is used instead of the `co_firstlineno` and `co_lnotab` attributes of the code object.

dis.findlabels(*code*)

Detect all offsets in the raw compiled bytecode string *code* which are jump targets, and return a list of these offsets.

dis.stack_effect(*opcode*, *oparg=None*, *, *jump=None*)

Compute the stack effect of *opcode* with argument *oparg*.

If the code has a jump target and *jump* is `True`, **`stack_effect()`** will return the stack effect of jumping. If *jump* is `False`, it will return the stack effect of not jumping. And if *jump* is `None` (default), it will return the maximal stack effect of both cases.

New in version 3.4.

Changed in version 3.8: Added *jump* parameter.

Python Bytecode Instructions

The **`get_instructions()`** function and **`Bytecode`** class provide details of bytecode instructions as **`Instruction`** instances:

class dis.Instruction

Details for a bytecode operation

opcode

numeric code for operation, corresponding to the opcode values listed below and the bytecode values in the Opcode collections.

opname

human readable name for operation

arg

numeric argument to operation (if any), otherwise `None`

argval

resolved arg value (if any), otherwise `None`

argrepr

human readable description of operation argument (if any), otherwise an empty string.

offset

start index of operation within bytecode sequence

starts_line

line started by this opcode (if any), otherwise `None`

is_jump_target

`True` if other code jumps to here, otherwise `False`

positions

`dis.Positions` object holding the start and end locations that are covered by this instruction.

New in version 3.4.

Changed in version 3.11: Field `positions` is added.

class dis.Positions

In case the information is not available, some fields might be `None`.

lineno

end_lineno

col_offset

end_col_offset

New in version 3.11.

The Python compiler currently generates the following bytecode instructions.

General instructions

NOP

Do nothing code. Used as a placeholder by the bytecode optimizer, and to generate line tracing events.

POP_TOP

Removes the top-of-stack (TOS) item.

COPY(*i*)

Push the *i*-th item to the top of the stack. The item is not removed from its original location.

New in version 3.11.

SWAP(*i*)

Swap TOS with the item at position *i*.

New in version 3.11.

CACHE

Rather than being an actual instruction, this opcode is used to mark extra space for the interpreter to cache useful data directly in the bytecode itself. It is automatically hidden by all `dis` utilities, but can be viewed with `show_caches=True`.

Logically, this space is part of the preceding instruction. Many opcodes expect to be followed by an exact number of caches, and will instruct the interpreter to skip over them at runtime.

Populated caches can look like arbitrary instructions, so great

care should be taken when reading or modifying raw, adaptive bytecode containing quickened data.

New in version 3.11.

Unary operations

Unary operations take the top of the stack, apply the operation, and push the result back on the stack.

UNARY_POSITIVE
: Implements `TOS = +TOS`.

UNARY_NEGATIVE
: Implements `TOS = -TOS`.

UNARY_NOT
: Implements `TOS = not TOS`.

UNARY_INVERT
: Implements `TOS = ~TOS`.

GET_ITER
: Implements `TOS = iter(TOS)`.

GET_YIELD_FROM_ITER
: If `TOS` is a generator iterator or coroutine object it is left as is. Otherwise, implements `TOS = iter(TOS)`.

  New in version 3.5.

Binary and in-place operations

Binary operations remove the top of the stack (TOS) and the second top-most stack item (TOS1) from the stack. They perform the operation, and put the result back on the stack.

In-place operations are like binary operations, in that they remove TOS and TOS1, and push the result back on the stack, but the

operation is done in-place when TOS1 supports it, and the resulting TOS may be (but does not have to be) the original TOS1.

BINARY_OP(*op*)

Implements the binary and in-place operators (depending on the value of *op*).

New in version 3.11.

BINARY_SUBSCR

Implements `TOS = TOS1[TOS]`.

STORE_SUBSCR

Implements `TOS1[TOS] = TOS2`.

DELETE_SUBSCR

Implements `del TOS1[TOS]`.

Coroutine opcodes

GET_AWAITABLE(*where*)

Implements `TOS = get_awaitable(TOS)`, where `get_awaitable(o)` returns `o` if `o` is a coroutine object or a generator object with the CO_ITERABLE_COROUTINE flag, or resolves `o.__await__`.

If the `where` operand is nonzero, it indicates where the instruction occurs:

- `1` After a call to `__aenter__`
- `2` After a call to `__aexit__`

New in version 3.5.

Changed in version 3.11: Previously, this instruction did not have an oparg.

GET_AITER

Implements `TOS = TOS.__aiter__()`.

New in version 3.5.

Changed in version 3.7: Returning awaitable objects from `__aiter__` is no longer supported.

GET_ANEXT

Pushes `get_awaitable(TOS.__anext__())` to the stack. See `GET_AWAITABLE` for details about `get_awaitable`.

New in version 3.5.

END_ASYNC_FOR

Terminates an **`async for`** loop. Handles an exception raised when awaiting a next item. If TOS is **`StopAsyncIteration`** pop 3 values from the stack and restore the exception state using the second of them. Otherwise re-raise the exception using the value from the stack. An exception handler block is removed from the block stack.

New in version 3.8:

Changed in version 3.11: Exception representation on the stack now consist of one, not three, items.

BEFORE_ASYNC_WITH

Resolves `__aenter__` and `__aexit__` from the object on top of the stack. Pushes `__aexit__` and result of `__aenter__()` to the stack.

New in version 3.5.

Miscellaneous opcodes

PRINT_EXPR

Implements the expression statement for the interactive mode. TOS is removed from the stack and printed. In non-interactive mode, an expression statement is terminated with **`POP_TOP`**.

SET_ADD(*i*)

Calls `set.add(TOS1[-i], TOS)`. Used to implement set comprehensions.

LIST_APPEND(*i*)

Calls `list.append(TOS1[-i], TOS)`. Used to implement list comprehensions.

MAP_ADD(*i*)

Calls `dict.__setitem__(TOS1[-i], TOS1, TOS)`. Used to implement dict comprehensions.

New in version 3.1.

Changed in version 3.8: Map value is TOS and map key is TOS1. Before, those were reversed.

For all of the **SET_ADD**, **LIST_APPEND** and **MAP_ADD** instructions, while the added value or key/value pair is popped off, the container object remains on the stack so that it is available for further iterations of the loop.

RETURN_VALUE

Returns with TOS to the caller of the function.

YIELD_VALUE

Pops TOS and yields it from a generator.

SETUP_ANNOTATIONS

Checks whether `__annotations__` is defined in `locals()`, if not it is set up to an empty `dict`. This opcode is only emitted if a class or module body contains variable annotations statically.

New in version 3.6.

IMPORT_STAR

Loads all symbols not starting with `'_'` directly from the

module TOS to the local namespace. The module is popped after loading all names. This opcode implements `from module import *`.

POP_EXCEPT

Pops a value from the stack, which is used to restore the exception state.

> *Changed in version 3.11:* Exception representation on the stack now consist of one, not three, items.

RERAISE

Re-raises the exception currently on top of the stack. If oparg is non-zero, pops an additional value from the stack which is used to set `f_lasti` of the current frame.

New in version 3.9.

Changed in version 3.11: Exception representation on the stack now consist of one, not three, items.

PUSH_EXC_INFO

Pops a value from the stack. Pushes the current exception to the top of the stack. Pushes the value originally popped back to the stack. Used in exception handlers.

New in version 3.11.

CHECK_EXC_MATCH

Performs exception matching for `except`. Tests whether the TOS1 is an exception matching TOS. Pops TOS and pushes the boolean result of the test.

New in version 3.11.

CHECK_EG_MATCH

Performs exception matching for `except*`. Applies `split(TOS)` on the exception group representing TOS1.

In case of a match, pops two items from the stack and pushes the non-matching subgroup (`None` in case of full match) followed by the matching subgroup. When there is no match, pops one item (the match type) and pushes `None`.

New in version 3.11.

PREP_RERAISE_STAR

Combines the raised and reraised exceptions list from TOS, into an exception group to propagate from a try-except* block. Uses the original exception group from TOS1 to reconstruct the structure of reraised exceptions. Pops two items from the stack and pushes the exception to reraise or `None` if there isn't one.

New in version 3.11.

WITH_EXCEPT_START

Calls the function in position 4 on the stack with arguments (type, val, tb) representing the exception at the top of the stack. Used to implement the call `context_manager.__exit__(*exc_info())` when an exception has occurred in a **`with`** statement.

New in version 3.9.

Changed in version 3.11: The `__exit__` function is in position 4 of the stack rather than 7. Exception representation on the stack now consist of one, not three, items.

LOAD_ASSERTION_ERROR

Pushes **`AssertionError`** onto the stack. Used by the **`assert`** statement.

New in version 3.9.

LOAD_BUILD_CLASS

Pushes **`builtins.__build_class__()`** onto the stack. It is later called to construct a class.

BEFORE_WITH(*delta*)

This opcode performs several operations before a with block starts. First, it loads **__exit__()** from the context manager and pushes it onto the stack for later use by **WITH_EXCEPT_START**. Then, **__enter__()** is called. Finally, the result of calling the `__enter__()` method is pushed onto the stack.

New in version 3.11.

GET_LEN

Push `len(TOS)` onto the stack.

New in version 3.10.

MATCH_MAPPING

If TOS is an instance of **collections.abc.Mapping** (or, more technically: if it has the **Py_TPFLAGS_MAPPING** flag set in its **tp_flags**), push `True` onto the stack. Otherwise, push `False`.

New in version 3.10.

MATCH_SEQUENCE

If TOS is an instance of **collections.abc.Sequence** and is *not* an instance of **str**/**bytes**/**bytearray** (or, more technically: if it has the **Py_TPFLAGS_SEQUENCE** flag set in its **tp_flags**), push `True` onto the stack. Otherwise, push `False`.

New in version 3.10.

MATCH_KEYS

TOS is a tuple of mapping keys, and TOS1 is the match subject. If TOS1 contains all of the keys in TOS, push a **tuple** containing the corresponding values. Otherwise, push `None`.

New in version 3.10.

Changed in version 3.11: Previously, this instruction also pushed a boolean value indicating success (`True`) or failure (`False`).

STORE_NAME(*namei*)

Implements `name = TOS`. *namei* is the index of *name* in the attribute **co_names** of the code object. The compiler tries to use **STORE_FAST** or **STORE_GLOBAL** if possible.

DELETE_NAME(*namei*)

Implements `del name`, where *namei* is the index into **co_names** attribute of the code object.

UNPACK_SEQUENCE(*count*)

Unpacks TOS into *count* individual values, which are put onto the stack right-to-left.

UNPACK_EX(*counts*)

Implements assignment with a starred target: Unpacks an iterable in TOS into individual values, where the total number of values can be smaller than the number of items in the iterable: one of the new values will be a list of all leftover items.

The low byte of *counts* is the number of values before the list value, the high byte of *counts* the number of values after it. The resulting values are put onto the stack right-to-left.

STORE_ATTR(*namei*)

Implements `TOS.name = TOS1`, where *namei* is the index of name in **co_names**.

DELETE_ATTR(*namei*)

Implements `del TOS.name`, using *namei* as index into **co_names**.

STORE_GLOBAL(*namei*)

Works as **`STORE_NAME`**, but stores the name as a global.

DELETE_GLOBAL(*namei*)

Works as **`DELETE_NAME`**, but deletes a global name.

LOAD_CONST(*consti*)

Pushes `co_consts[consti]` onto the stack.

LOAD_NAME(*namei*)

Pushes the value associated with `co_names[namei]` onto the stack.

BUILD_TUPLE(*count*)

Creates a tuple consuming *count* items from the stack, and pushes the resulting tuple onto the stack.

BUILD_LIST(*count*)

Works as **`BUILD_TUPLE`**, but creates a list.

BUILD_SET(*count*)

Works as **`BUILD_TUPLE`**, but creates a set.

BUILD_MAP(*count*)

Pushes a new dictionary object onto the stack. Pops `2 * count` items so that the dictionary holds *count* entries: `{..., TOS3: TOS2, TOS1: TOS}`.

Changed in version 3.5: The dictionary is created from stack items instead of creating an empty dictionary pre-sized to hold *count* items.

BUILD_CONST_KEY_MAP(*count*)

The version of **`BUILD_MAP`** specialized for constant keys. Pops the top element on the stack which contains a tuple of

keys, then starting from `TOS1`, pops *count* values to form values in the built dictionary.

New in version 3.6.

BUILD_STRING(*count*)

Concatenates *count* strings from the stack and pushes the resulting string onto the stack.

New in version 3.6.

LIST_TO_TUPLE

Pops a list from the stack and pushes a tuple containing the same values.

New in version 3.9.

LIST_EXTEND(*i*)

Calls `list.extend(TOS1[-i], TOS)`. Used to build lists.

New in version 3.9.

SET_UPDATE(*i*)

Calls `set.update(TOS1[-i], TOS)`. Used to build sets.

New in version 3.9.

DICT_UPDATE(*i*)

Calls `dict.update(TOS1[-i], TOS)`. Used to build dicts.

New in version 3.9.

DICT_MERGE(*i*)

Like **`DICT_UPDATE`** but raises an exception for duplicate keys.

New in version 3.9.

LOAD_ATTR(*namei*)

Replaces TOS with `getattr(TOS, co_names[namei])`.

COMPARE_OP(*opname*)

Performs a Boolean operation. The operation name can be found in `cmp_op[opname]`.

IS_OP(*invert*)

Performs `is` comparison, or `is not` if `invert` is 1.

New in version 3.9.

CONTAINS_OP(*invert*)

Performs `in` comparison, or `not in` if `invert` is 1.

New in version 3.9.

IMPORT_NAME(*namei*)

Imports the module `co_names[namei]`. TOS and TOS1 are popped and provide the *fromlist* and *level* arguments of **`__import__()`**. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent **`STORE_FAST`** instruction modifies the namespace.

IMPORT_FROM(*namei*)

Loads the attribute `co_names[namei]` from the module found in TOS. The resulting object is pushed onto the stack, to be subsequently stored by a **`STORE_FAST`** instruction.

JUMP_FORWARD(*delta*)

Increments bytecode counter by *delta*.

JUMP_BACKWARD(*delta*)

Decrements bytecode counter by *delta*. Checks for interrupts.

New in version 3.11.

JUMP_BACKWARD_NO_INTERRUPT(*delta*)

Decrements bytecode counter by *delta*. Does not check for interrupts.

New in version 3.11.

POP_JUMP_FORWARD_IF_TRUE(*delta*)

If TOS is true, increments the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

POP_JUMP_BACKWARD_IF_TRUE(*delta*)

If TOS is true, decrements the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

POP_JUMP_FORWARD_IF_FALSE(*delta*)

If TOS is false, increments the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

POP_JUMP_BACKWARD_IF_FALSE(*delta*)

If TOS is false, decrements the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

POP_JUMP_FORWARD_IF_NOT_NONE(*delta*)

If TOS is not `None`, increments the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

POP_JUMP_BACKWARD_IF_NOT_NONE(*delta*)

If TOS is not `None`, decrements the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

POP_JUMP_FORWARD_IF_NONE(*delta*)

If TOS is `None`, increments the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

POP_JUMP_BACKWARD_IF_NONE(*delta*)

If TOS is `None`, decrements the bytecode counter by *delta*. TOS is popped.

New in version 3.11.

JUMP_IF_TRUE_OR_POP(*delta*)

If TOS is true, increments the bytecode counter by *delta* and leaves TOS on the stack. Otherwise (TOS is false), TOS is popped.

New in version 3.1.

Changed in version 3.11: The oparg is now a relative delta rather than an absolute target.

JUMP_IF_FALSE_OR_POP(*delta*)

If TOS is false, increments the bytecode counter by *delta* and leaves TOS on the stack. Otherwise (TOS is true), TOS is popped.

New in version 3.1.

Changed in version 3.11: The oparg is now a relative delta rather than an absolute target.

FOR_ITER(*delta*)

TOS is an iterator. Call its `__next__()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted, TOS is popped, and the byte code counter is incremented by *delta*.

LOAD_GLOBAL(*namei*)

Loads the global named `co_names[namei>>1]` onto the stack.

Changed in version 3.11: If the low bit of `namei` is set, then a `NULL` is pushed to the stack before the global variable.

LOAD_FAST(*var_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack.

STORE_FAST(*var_num*)

Stores TOS into the local `co_varnames[var_num]`.

DELETE_FAST(*var_num*)

Deletes local `co_varnames[var_num]`.

MAKE_CELL(*i*)

Creates a new cell in slot `i`. If that slot is empty then that value is stored into the new cell.

New in version 3.11.

LOAD_CLOSURE(*i*)

Pushes a reference to the cell contained in slot `i` of the “fast locals” storage. The name of the variable is `co_fastlocalnames[i]`.

Note that `LOAD_CLOSURE` is effectively an alias for `LOAD_FAST`. It exists to keep bytecode a little more readable.

Changed in version 3.11: `i` is no longer offset by the length of `co_varnames`.

LOAD_DEREF(*i*)

Loads the cell contained in slot `i` of the "fast locals" storage. Pushes a reference to the object the cell contains on the stack.

Changed in version 3.11: `i` is no longer offset by the length of `co_varnames`.

LOAD_CLASSDEREF(*i*)

Much like **`LOAD_DEREF`** but first checks the locals dictionary before consulting the cell. This is used for loading free variables in class bodies.

New in version 3.4.

Changed in version 3.11: `i` is no longer offset by the length of `co_varnames`.

STORE_DEREF(*i*)

Stores TOS into the cell contained in slot `i` of the "fast locals" storage.

Changed in version 3.11: `i` is no longer offset by the length of `co_varnames`.

DELETE_DEREF(*i*)

Empties the cell contained in slot `i` of the "fast locals" storage. Used by the **`del`** statement.

New in version 3.2.

Changed in version 3.11: `i` is no longer offset by the length of `co_varnames`.

COPY_FREE_VARS(*n*)

Copies the `n` free variables from the closure into the frame.

Removes the need for special code on the caller's side when calling closures.

New in version 3.11.

RAISE_VARARGS(*argc*)

Raises an exception using one of the 3 forms of the `raise` statement, depending on the value of *argc*:

- 0: `raise` (re-raise previous exception)
- 1: `raise TOS` (raise exception instance or type at `TOS`)
- 2: `raise TOS1 from TOS` (raise exception instance or type at `TOS1` with `__cause__` set to `TOS`)

CALL(*argc*)

Calls a callable object with the number of arguments specified by `argc`, including the named arguments specified by the preceding **`KW_NAMES`**, if any. On the stack are (in ascending order), either:

- NULL
- The callable
- The positional arguments
- The named arguments

or:

- The callable
- `self`
- The remaining positional arguments
- The named arguments

`argc` is the total of the positional and named arguments, excluding `self` when a `NULL` is not present.

`CALL` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

New in version 3.11.

CALL_FUNCTION_EX(*flags*)

Calls a callable object with variable set of positional and keyword arguments. If the lowest bit of *flags* is set, the top of the stack contains a mapping object containing additional keyword arguments. Before the callable is called, the mapping object and iterable object are each “unpacked” and their contents passed in as keyword and positional arguments respectively. `CALL_FUNCTION_EX` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

New in version 3.6.

LOAD_METHOD(*namei*)

Loads a method named `co_names[namei]` from the TOS object. TOS is popped. This bytecode distinguishes two cases: if TOS has a method with the correct name, the bytecode pushes the unbound method and TOS. TOS will be used as the first argument (`self`) by **`CALL`** when calling the unbound method. Otherwise, `NULL` and the object return by the attribute lookup are pushed.

New in version 3.7.

PRECALL(*argc*)

Prefixes **`CALL`**. Logically this is a no op. It exists to enable effective specialization of calls. `argc` is the number of arguments as described in **`CALL`**.

New in version 3.11.

PUSH_NULL

Pushes a `NULL` to the stack. Used in the call sequence to match the `NULL` pushed by **`LOAD_METHOD`** for non-method calls.

New in version 3.11.

KW_NAMES(*i*)

Prefixes **PRECALL**. Stores a reference to `co_consts[consti]` into an internal variable for use by **CALL**. `co_consts[consti]` must be a tuple of strings.

New in version 3.11.

MAKE_FUNCTION(*flags*)

Pushes a new function object on the stack. From bottom to top, the consumed stack must consist of values if the argument carries a specified flag value

- `0x01` a tuple of default values for positional-only and positional-or-keyword parameters in positional order
- `0x02` a dictionary of keyword-only parameters' default values
- `0x04` a tuple of strings containing parameters' annotations
- `0x08` a tuple containing cells for free variables, making a closure
- the code associated with the function (at TOS1)
- the qualified name of the function (at TOS)

Changed in version 3.10: Flag value `0x04` is a tuple of strings instead of dictionary

BUILD_SLICE(*argc*)

Pushes a slice object on the stack. *argc* must be 2 or 3. If it is 2, `slice(TOS1, TOS)` is pushed; if it is 3, `slice(TOS2, TOS1, TOS)` is pushed. See the **slice()** built-in function for more information.

EXTENDED_ARG(*ext*)

Prefixes any opcode which has an argument too big to fit into the default one byte. *ext* holds an additional byte which act as higher bits in the argument. For each opcode, at most three

prefixal `EXTENDED_ARG` are allowed, forming an argument from two-byte to four-byte.

FORMAT_VALUE(*flags*)

Used for implementing formatted literal strings (f-strings). Pops an optional *fmt_spec* from the stack, then a required *value*. *flags* is interpreted as follows:

- `(flags & 0x03) == 0x00`: *value* is formatted as-is.
- `(flags & 0x03) == 0x01`: call **`str()`** on *value* before formatting it.
- `(flags & 0x03) == 0x02`: call **`repr()`** on *value* before formatting it.
- `(flags & 0x03) == 0x03`: call **`ascii()`** on *value* before formatting it.
- `(flags & 0x04) == 0x04`: pop *fmt_spec* from the stack and use it, else use an empty *fmt_spec*.

Formatting is performed using **`PyObject_Format()`**. The result is pushed on the stack.

New in version 3.6.

MATCH_CLASS(*count*)

TOS is a tuple of keyword attribute names, TOS1 is the class being matched against, and TOS2 is the match subject. *count* is the number of positional sub-patterns.

Pop TOS, TOS1, and TOS2. If TOS2 is an instance of TOS1 and has the positional and keyword attributes required by *count* and TOS, push a tuple of extracted attributes. Otherwise, push `None`.

New in version 3.10.

Changed in version 3.11: Previously, this instruction also pushed a boolean value indicating success (`True`) or failure (`False`).

RESUME(*where*)

A no-op. Performs internal tracing, debugging and optimization checks.

The `where` operand marks where the `RESUME` occurs:

- `0` The start of a function
- `1` After a `yield` expression
- `2` After a `yield from` expression
- `3` After an `await` expression

New in version 3.11.

RETURN_GENERATOR

Create a generator, coroutine, or async generator from the current frame. Clear the current frame and return the newly created generator.

New in version 3.11.

SEND

Sends `None` to the sub-generator of this generator. Used in `yield from` and `await` statements.

New in version 3.11.

ASYNC_GEN_WRAP

Wraps the value on top of the stack in an `async_generator_wrapped_value`. Used to yield in async generators.

New in version 3.11.

HAVE_ARGUMENT

This is not really an opcode. It identifies the dividing line between opcodes which don't use their argument and those that do (`< HAVE_ARGUMENT` and `>= HAVE_ARGUMENT`, respectively).

Changed in version 3.6: Now every instruction has an

argument, but opcodes `< HAVE_ARGUMENT` ignore it. Before, only opcodes `>= HAVE_ARGUMENT` had an argument.

Opcode collections

These collections are provided for automatic introspection of bytecode instructions:

dis.opname
: Sequence of operation names, indexable using the bytecode.

dis.opmap
: Dictionary mapping operation names to bytecodes.

dis.cmp_op
: Sequence of all compare operation names.

dis.hasconst
: Sequence of bytecodes that access a constant.

dis.hasfree
: Sequence of bytecodes that access a free variable (note that 'free' in this context refers to names in the current scope that are referenced by inner scopes or names in outer scopes that are referenced from this scope. It does *not* include references to global or builtin scopes).

dis.hasname
: Sequence of bytecodes that access an attribute by name.

dis.hasjrel
: Sequence of bytecodes that have a relative jump target.

dis.hasjabs
: Sequence of bytecodes that have an absolute jump target.

dis.haslocal

Sequence of bytecodes that access a local variable.

dis.hascompare
: Sequence of bytecodes of Boolean operations.

`pickletools` — Tools for pickle developers

Source code: Lib/pickletools.py [https://github.com/python/cpython/tree/3.11/Lib/pickletools.py]

This module contains various constants relating to the intimate details of the `pickle` module, some lengthy comments about the implementation, and a few useful functions for analyzing pickled data. The contents of this module are useful for Python core developers who are working on the `pickle`; ordinary users of the `pickle` module probably won't find the `pickletools` module relevant.

Command line usage

New in version 3.2.

When invoked from the command line, `python -m pickletools` will disassemble the contents of one or more pickle files. Note that if you want to see the Python object stored in the pickle rather than the details of pickle format, you may want to use `-m pickle` instead. However, when the pickle file that you want to examine comes from an untrusted source, `-m pickletools` is a safer option because it does not execute pickle bytecode.

For example, with a tuple `(1, 2)` pickled in file `x.pickle`:

```
$ python -m pickle x.pickle
(1, 2)

$ python -m pickletools x.pickle
    0: \x80 PROTO      3
    2: K    BININT1    1
```

```
    4: K    BININT1    2
    6: \x86 TUPLE2
    7: q    BINPUT     0
    9: .    STOP
highest protocol among opcodes = 2
```

Command line options

-a, --annotate

Annotate each line with a short opcode description.

-o, --output=<file>

Name of a file where the output should be written.

-l, --indentlevel=<num>

The number of blanks by which to indent a new MARK level.

-m, --memo

When multiple objects are disassembled, preserve memo between disassemblies.

-p, --preamble=<preamble>

When more than one pickle file are specified, print given preamble before each disassembly.

Programmatic Interface

pickletools.dis(*pickle*, *out=None*, *memo=None*, *indentlevel=4*, *annotate=0*)

Outputs a symbolic disassembly of the pickle to the file-like object *out*, defaulting to `sys.stdout`. *pickle* can be a string or a file-like object. *memo* can be a Python dictionary that will be used as the pickle's memo; it can be used to perform disassemblies across multiple pickles created by the same pickler. Successive levels, indicated by `MARK` opcodes in the stream, are indented by *indentlevel* spaces. If a nonzero value is given to *annotate*, each opcode in the output is annotated

with a short description. The value of *annotate* is used as a hint for the column where annotation should start.

New in version 3.2: The *annotate* argument.

pickletools.genops(*pickle*)

Provides an iterator over all of the opcodes in a pickle, returning a sequence of `(opcode, arg, pos)` triples. *opcode* is an instance of an **`OpcodeInfo`** class; *arg* is the decoded value, as a Python object, of the opcode's argument; *pos* is the position at which this opcode is located. *pickle* can be a string or a file-like object.

pickletools.optimize(*picklestring*)

Returns a new equivalent pickle string after eliminating unused `PUT` opcodes. The optimized pickle is shorter, takes less transmission time, requires less storage space, and unpickles more efficiently.

MS Windows Specific Services

This chapter describes modules that are only available on MS Windows platforms.

- **msvcrt** — Useful routines from the MS VC++ runtime
  - File Operations
  - Console I/O
  - Other Functions
- **winreg** — Windows registry access
  - Functions
  - Constants
    - HKEY_* Constants
    - Access Rights
      - 64-bit Specific
    - Value Types
  - Registry Handle Objects
- **winsound** — Sound-playing interface for Windows

`msvcrt` — Useful routines from the MS VC++ runtime

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the `getpass` module uses this in the implementation of the `getpass()` function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible.

Changed in version 3.3: Operations in this module now raise `OSError` where `IOError` was raised.

File Operations

msvcrt.locking(*fd*, *mode*, *nbytes*)

Lock part of a file based on file descriptor *fd* from the C runtime. Raises `OSError` on failure. The locked region of the file extends from the current file position for *nbytes* bytes, and may continue beyond the end of the file. *mode* must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

Raises an auditing event `msvcrt.locking` with arguments `fd`, `mode`, `nbytes`.

msvcrt.LK_LOCK
msvcrt.LK_RLCK

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, **OSError** is raised.

msvcrt.LK_NBLCK
msvcrt.LK_NBRLCK

Locks the specified bytes. If the bytes cannot be locked, **OSError** is raised.

msvcrt.LK_UNLCK

Unlocks the specified bytes, which must have been previously locked.

msvcrt.setmode(*fd*, *flags*)

Set the line-end translation mode for the file descriptor *fd*. To set it to text mode, *flags* should be **os.O_TEXT**; for binary, it should be **os.O_BINARY**.

msvcrt.open_osfhandle(*handle*, *flags*)

Create a C runtime file descriptor from the file handle *handle*. The *flags* parameter should be a bitwise OR of **os.O_APPEND**, **os.O_RDONLY**, and **os.O_TEXT**. The returned file descriptor may be used as a parameter to **os.fdopen()** to create a file object.

Raises an auditing event `msvcrt.open_osfhandle` with arguments `handle`, `flags`.

msvcrt.get_osfhandle(*fd*)

Return the file handle for the file descriptor *fd*. Raises **OSError** if *fd* is not recognized.

Raises an auditing event `msvcrt.get_osfhandle` with argument `fd`.

Console I/O

msvcrt.kbhit()

Return `True` if a keypress is waiting to be read.

msvcrt.getch()

Read a keypress and return the resulting character as a byte string. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for `Enter` to be pressed. If the pressed key was a special function key, this will return `'\000'` or `'\xe0'`; the next call will return the keycode. The `Control-C` keypress cannot be read with this function.

msvcrt.getwch()

Wide char variant of **`getch()`**, returning a Unicode value.

msvcrt.getche()

Similar to **`getch()`**, but the keypress will be echoed if it represents a printable character.

msvcrt.getwche()

Wide char variant of **`getche()`**, returning a Unicode value.

msvcrt.putch(*char*)

Print the byte string *char* to the console without buffering.

msvcrt.putwch(*unicode_char*)

Wide char variant of **`putch()`**, accepting a Unicode value.

msvcrt.ungetch(*char*)

Cause the byte string *char* to be “pushed back” into the console buffer; it will be the next character read by **`getch()`** or **`getche()`**.

msvcrt.ungetwch(*unicode_char*)

Wide char variant of **`ungetch()`**, accepting a Unicode value.

Other Functions

msvcrt.heapmin()

Force the **`malloc()`** heap to clean itself up and return unused blocks to the operating system. On failure, this raises **`OSError`**.

`winreg` — Windows registry access

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a handle object is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

Changed in version 3.3: Several functions in this module used to raise a `WindowsError`, which is now an alias of `OSError`.

Functions

This module offers the following functions:

winreg.CloseKey(*hkey*)

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

Note

If *hkey* is not closed using this method (or via `hkey.Close()`), it is closed when the *hkey* object is destroyed by Python.

winreg.ConnectRegistry(*computer_name*, *key*)

Establishes a connection to a predefined registry handle on another computer, and returns a handle object.

computer_name is the name of the remote computer, of the form `r"\\computername"`. If `None`, the local computer is used.

key is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an **OSError** exception is raised.

Raises an auditing event `winreg.ConnectRegistry` with arguments `computer_name`, `key`.

Changed in version 3.3: See above.

winreg.CreateKey(*key*, *sub_key*)

Creates or opens the specified key, returning a handle object.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that names the key this method opens or creates.

If *key* is one of the predefined keys, *sub_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an **OSError** exception is raised.

Raises an auditing event `winreg.CreateKey` with arguments `key`, `sub_key`, `access`.

Raises an auditing event `winreg.OpenKey/result` with argument `key`.

Changed in version 3.3: See above.

winreg.CreateKeyEx(*key*, *sub_key*, *reserved=0*, *access=KEY_WRITE*)

Creates or opens the specified key, returning a handle object.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that names the key this method opens or creates.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is **KEY_WRITE**. See Access Rights for other allowed values.

If *key* is one of the predefined keys, *sub_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an **OSError** exception is raised.

Raises an auditing event `winreg.CreateKey` with arguments `key`, `sub_key`, `access`.

Raises an auditing event `winreg.OpenKey/result` with argument `key`.

New in version 3.2.

Changed in version 3.3: See above.

winreg.DeleteKey(*key*, *sub_key*)

Deletes the specified key.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

This method can not delete keys with subkeys.

If the method succeeds, the entire key, including all of its

values, is removed. If the method fails, an **OSError** exception is raised.

Raises an auditing event `winreg.DeleteKey` with arguments `key`, `sub_key`, `access`.

Changed in version 3.3: See above.

winreg.DeleteKeyEx(*key*, *sub_key*, *access=KEY_WOW64_64KEY*, *reserved=0*)

Deletes the specified key.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is **KEY_WOW64_64KEY**. On 32-bit Windows, the WOW64 constants are ignored. See Access Rights for other allowed values.

This method can not delete keys with subkeys.

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an **OSError** exception is raised.

On unsupported Windows versions, **NotImplementedError** is raised.

Raises an auditing event `winreg.DeleteKey` with arguments `key`, `sub_key`, `access`.

New in version 3.2.

Changed in version 3.3: See above.

winreg.DeleteValue(*key*, *value*)

Removes a named value from a registry key.

key is an already open key, or one of the predefined HKEY_* constants.

value is a string that identifies the value to remove.

Raises an auditing event `winreg.DeleteValue` with arguments `key, value`.

winreg.EnumKey(*key*, *index*)

Enumerates subkeys of an open registry key, returning a string.

key is an already open key, or one of the predefined HKEY_* constants.

index is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until an **`OSError`** exception is raised, indicating, no more values are available.

Raises an auditing event `winreg.EnumKey` with arguments `key, index`.

Changed in version 3.3: See above.

winreg.EnumValue(*key*, *index*)

Enumerates values of an open registry key, returning a tuple.

key is an already open key, or one of the predefined HKEY_* constants.

index is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until an **OSError** exception is raised, indicating no more values.

The result is a tuple of 3 items:

Index	Meaning
0	A string that identifies the value name
1	An object that holds the value data, and whose type depends on the underlying registry type
2	An integer that identifies the type of the value data (see table in docs for **SetValueEx()**)

Raises an auditing event `winreg.EnumValue` with arguments `key, index`.

Changed in version 3.3: See above.

winreg.ExpandEnvironmentStrings(*str*)

Expands environment variable placeholders `%NAME%` in strings like **REG_EXPAND_SZ**:

```
>>> ExpandEnvironmentStrings('%windir%')
'C:\\Windows'
```

Raises an auditing event `winreg.ExpandEnvironmentStrings` with argument `str`.

winreg.FlushKey(*key*)

Writes all the attributes of a key to the registry.

key is an already open key, or one of the predefined HKEY_* constants.

It is not necessary to call **FlushKey()** to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike **CloseKey()**, the **FlushKey()** method returns only when all the data has been written to the

registry. An application should only call **FlushKey()** if it requires absolute certainty that registry changes are on disk.

Note

If you don't know whether a **FlushKey()** call is required, it probably isn't.

winreg.LoadKey(*key*, *sub_key*, *file_name*)

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

key is a handle returned by **ConnectRegistry()** or one of the constants **HKEY_USERS** or **HKEY_LOCAL_MACHINE**.

sub_key is a string that identifies the subkey to load.

file_name is the name of the file to load registry data from. This file must have been created with the **SaveKey()** function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to **LoadKey()** fails if the calling process does not have the **SE_RESTORE_PRIVILEGE** privilege. Note that privileges are different from permissions – see the RegLoadKey documentation [https://msdn.microsoft.com/en-us/library/ms724889%28v=VS.85%29.aspx] for more details.

If *key* is a handle returned by **ConnectRegistry()**, then the path specified in *file_name* is relative to the remote computer.

Raises an auditing event `winreg.LoadKey` with arguments `key`, `sub_key`, `file_name`.

winreg.OpenKey(*key*, *sub_key*, *reserved=0*, *access=KEY_READ*)
winreg.OpenKeyEx(*key*, *sub_key*, *reserved=0*, *access=KEY_READ*)

Opens the specified key, returning a handle object.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that identifies the sub_key to open.

reserved is a reserved integer, and must be zero. The default is zero.

access is an integer that specifies an access mask that describes the desired security access for the key. Default is **KEY_READ**. See Access Rights for other allowed values.

The result is a new handle to the specified key.

If the function fails, **OSError** is raised.

Raises an auditing event `winreg.OpenKey` with arguments `key, sub_key, access`.

Raises an auditing event `winreg.OpenKey/result` with argument `key`.

Changed in version 3.2: Allow the use of named arguments.

Changed in version 3.3: See above.

winreg.QueryInfoKey(*key*)

Returns information about a key, as a tuple.

key is an already open key, or one of the predefined HKEY_* constants.

The result is a tuple of 3 items:

Index	Meaning
0	An integer giving the number of sub keys this key has.
1	An integer giving the number of values this key has.
2	An integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1601.

Raises an auditing event `winreg.QueryInfoKey` with argument `key`.

winreg.QueryValue(*key*, *sub_key*)

Retrieves the unnamed value for a key, as a string.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that holds the name of the subkey with which the value is associated. If this parameter is `None` or empty, the function retrieves the value set by the **`SetValue()`** method for the key identified by *key*.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a `NULL` name. But the underlying API call doesn't return the type, so always use **`QueryValueEx()`** if possible.

Raises an auditing event `winreg.QueryValue` with arguments `key`, `sub_key`, `value_name`.

winreg.QueryValueEx(*key*, *value_name*)

Retrieves the type and data for a specified value name associated with an open registry key.

key is an already open key, or one of the predefined HKEY_* constants.

value_name is a string indicating the value to query.

The result is a tuple of 2 items:

Index	Meaning
0	The value of the registry item.
1	An integer giving the registry type for this value (see table in docs for **`SetValueEx()`**)

Raises an auditing event `winreg.QueryValue` with arguments `key`, `sub_key`, `value_name`.

winreg.SaveKey(*key*, *file_name*)

Saves the specified key, and all its subkeys to the specified

file.

key is an already open key, or one of the predefined HKEY_* constants.

file_name is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the **`LoadKey()`** method.

If *key* represents a key on a remote computer, the path described by *file_name* is relative to the remote computer. The caller of this method must possess the **`SeBackupPrivilege`** security privilege. Note that privileges are different than permissions – see the Conflicts Between User Rights and Permissions documentation [https://msdn.microsoft.com/en-us/library/ms724878%28v=VS.85%29.aspx] for more details.

This function passes `NULL` for *security_attributes* to the API.

Raises an auditing event `winreg.SaveKey` with arguments `key, file_name`.

winreg.SetValue(*key*, *sub_key*, *type*, *value*)

Associates a value with a specified key.

key is an already open key, or one of the predefined HKEY_* constants.

sub_key is a string that names the subkey with which the value is associated.

type is an integer that specifies the type of the data. Currently this must be **`REG_SZ`**, meaning only strings are supported. Use the **`SetValueEx()`** function for support for other data types.

value is a string that specifies the new value.

If the key specified by the *sub_key* parameter does not exist, the SetValue function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the *key* parameter must have been opened with **KEY_SET_VALUE** access.

Raises an auditing event `winreg.SetValue` with arguments `key, sub_key, type, value`.

winreg.SetValueEx(*key*, *value_name*, *reserved*, *type*, *value*)

Stores data in the value field of an open registry key.

key is an already open key, or one of the predefined HKEY_* constants.

value_name is a string that names the subkey with which the value is associated.

reserved can be anything – zero is always passed to the API.

type is an integer that specifies the type of the data. See Value Types for the available types.

value is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the key parameter must have been opened with **KEY_SET_VALUE** access.

To open the key, use the **CreateKey()** or **OpenKey()** methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

Raises an auditing event `winreg.SetValue` with arguments

`key, sub_key, type, value`.

winreg.DisableReflectionKey(*key*)

Disables registry reflection for 32-bit processes running on a 64-bit operating system.

key is an already open key, or one of the predefined HKEY_* constants.

Will generally raise **`NotImplementedError`** if executed on a 32-bit operating system.

If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

Raises an auditing event `winreg.DisableReflectionKey` with argument `key`.

winreg.EnableReflectionKey(*key*)

Restores registry reflection for the specified disabled key.

key is an already open key, or one of the predefined HKEY_* constants.

Will generally raise **`NotImplementedError`** if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

Raises an auditing event `winreg.EnableReflectionKey` with argument `key`.

winreg.QueryReflectionKey(*key*)

Determines the reflection state for the specified key.

key is an already open key, or one of the predefined HKEY_* constants.

Returns `True` if reflection is disabled.

Will generally raise **`NotImplementedError`** if executed on a 32-bit operating system.

Raises an auditing event `winreg.QueryReflectionKey` with argument `key`.

Constants

The following constants are defined for use in many **`_winreg`** functions.

HKEY_* Constants

winreg.HKEY_CLASSES_ROOT

Registry entries subordinate to this key define types (or classes) of documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

winreg.HKEY_CURRENT_USER

Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

winreg.HKEY_LOCAL_MACHINE

Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

winreg.HKEY_USERS

Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

winreg.HKEY_PERFORMANCE_DATA

Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry; the registry functions cause the system to collect the data from its source.

winreg.HKEY_CURRENT_CONFIG

Contains information about the current hardware profile of the local computer system.

winreg.HKEY_DYN_DATA

This key is not used in versions of Windows after 98.

Access Rights

For more information, see Registry Key Security and Access [https://msdn.microsoft.com/en-us/library/ms724878%28v=VS.85%29.aspx].

winreg.KEY_ALL_ACCESS

Combines the STANDARD_RIGHTS_REQUIRED, **KEY_QUERY_VALUE**, **KEY_SET_VALUE**, **KEY_CREATE_SUB_KEY**, **KEY_ENUMERATE_SUB_KEYS**, **KEY_NOTIFY**, and **KEY_CREATE_LINK** access rights.

winreg.KEY_WRITE

Combines the STANDARD_RIGHTS_WRITE, **KEY_SET_VALUE**, and **KEY_CREATE_SUB_KEY** access rights.

winreg.KEY_READ

Combines the STANDARD_RIGHTS_READ, **KEY_QUERY_VALUE**, **KEY_ENUMERATE_SUB_KEYS**, and **KEY_NOTIFY** values.

winreg.KEY_EXECUTE

Equivalent to **KEY_READ**.

winreg.KEY_QUERY_VALUE

Required to query the values of a registry key.

winreg.KEY_SET_VALUE
: Required to create, delete, or set a registry value.

winreg.KEY_CREATE_SUB_KEY
: Required to create a subkey of a registry key.

winreg.KEY_ENUMERATE_SUB_KEYS
: Required to enumerate the subkeys of a registry key.

winreg.KEY_NOTIFY
: Required to request change notifications for a registry key or for subkeys of a registry key.

winreg.KEY_CREATE_LINK
: Reserved for system use.

64-bit Specific

For more information, see Accessing an Alternate Registry View [https://msdn.microsoft.com/en-us/library/aa384129(v=VS.85).aspx].

winreg.KEY_WOW64_64KEY
: Indicates that an application on 64-bit Windows should operate on the 64-bit registry view. On 32-bit Windows, this constant is ignored.

winreg.KEY_WOW64_32KEY
: Indicates that an application on 64-bit Windows should operate on the 32-bit registry view. On 32-bit Windows, this constant is ignored.

Value Types

For more information, see Registry Value Types [https://msdn.microsoft.com/en-us/library/ms724884%28v=VS.85%29.aspx].

winreg.REG_BINARY

Binary data in any form.

winreg.REG_DWORD
: 32-bit number.

winreg.REG_DWORD_LITTLE_ENDIAN
: A 32-bit number in little-endian format. Equivalent to **REG_DWORD**.

winreg.REG_DWORD_BIG_ENDIAN
: A 32-bit number in big-endian format.

winreg.REG_EXPAND_SZ
: Null-terminated string containing references to environment variables (`%PATH%`).

winreg.REG_LINK
: A Unicode symbolic link.

winreg.REG_MULTI_SZ
: A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

winreg.REG_NONE
: No defined value type.

winreg.REG_QWORD
: A 64-bit number.

  New in version 3.6.

winreg.REG_QWORD_LITTLE_ENDIAN
: A 64-bit number in little-endian format. Equivalent to **REG_QWORD**.

  New in version 3.6.

winreg.REG_RESOURCE_LIST
: A device-driver resource list.

winreg.REG_FULL_RESOURCE_DESCRIPTOR
: A hardware setting.

winreg.REG_RESOURCE_REQUIREMENTS_LIST
: A hardware resource list.

winreg.REG_SZ
: A null-terminated string.

Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the **`Close()`** method on the object, or the **`CloseKey()`** function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for **`__bool__()`** – thus

```
if handle:
    print("Yes")
```

will print `Yes` if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the built-in **`int()`** function), in which case the underlying Windows handle

value is returned. You can also use the **Detach()** method to return the integer handle, and also disconnect the Windows handle from the handle object.

PyHKEY.Close()

Closes the underlying Windows handle.

If the handle is already closed, no error is raised.

PyHKEY.Detach()

Detaches the Windows handle from the handle object.

The result is an integer that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

Raises an auditing event `winreg.PyHKEY.Detach` with argument `key`.

PyHKEY._enter_()
PyHKEY._exit_(**exc_info*)

The HKEY object implements **__enter__()** and **__exit__()** and thus supports the context protocol for the **with** statement:

```
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ...  # work with key
```

will automatically close *key* when control leaves the **with** block.

`winsound` — Sound-playing interface for Windows

The `winsound` module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

winsound.Beep(*frequency*, *duration*)

Beep the PC's speaker. The *frequency* parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The *duration* parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, `RuntimeError` is raised.

winsound.PlaySound(*sound*, *flags*)

Call the underlying `PlaySound()` function from the Platform API. The *sound* parameter may be a filename, a system sound alias, audio data as a bytes-like object, or `None`. Its interpretation depends on the value of *flags*, which can be a bitwise ORed combination of the constants described below. If the *sound* parameter is `None`, any currently playing waveform sound is stopped. If the system indicates an error, `RuntimeError` is raised.

winsound.MessageBeep(*type*=*MB_OK*)

Call the underlying `MessageBeep()` function from the Platform API. This plays a sound as specified in the registry. The *type* argument specifies which sound to play; possible values are `-1`, `MB_ICONASTERISK`, `MB_ICONEXCLAMATION`, `MB_ICONHAND`, `MB_ICONQUESTION`, and `MB_OK`, all described below. The value `-1` produces a "simple beep"; this is the final fallback if a sound cannot be played otherwise. If the system indicates

an error, **RuntimeError** is raised.

winsound.SND_FILENAME

The *sound* parameter is the name of a WAV file. Do not use with **SND_ALIAS**.

winsound.SND_ALIAS

The *sound* parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless **SND_NODEFAULT** is also specified. If no default sound is registered, raise **RuntimeError**. Do not use with **SND_FILENAME**.

All Win32 systems support at least the following; most systems support many more:

PlaySound(), name	Corresponding Control Panel Sound name
'SystemAsterisk'	Asterisk
'SystemExclamation'	Exclamation
'SystemExit'	Exit Windows
'SystemHand'	Critical Stop
'SystemQuestion'	Question

For example:

```
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS

# Probably play Windows default sound, if any is re
# "*" probably isn't the registered name of any sou
winsound.PlaySound("*", winsound.SND_ALIAS)
```

winsound.SND_LOOP

Play the sound repeatedly. The **SND_ASYNC** flag must also be used to avoid blocking. Cannot be used with **SND_MEMORY**.

winsound.SND_MEMORY

The *sound* parameter to **PlaySound()** is a memory image of

a WAV file, as a bytes-like object.

Note

This module does not support playing from a memory image asynchronously, so a combination of this flag and **SND_ASYNC** will raise **RuntimeError**.

winsound.SND_PURGE

Stop playing all instances of the specified sound.

Note

This flag is not supported on modern Windows platforms.

winsound.SND_ASYNC

Return immediately, allowing sounds to play asynchronously.

winsound.SND_NODEFAULT

If the specified sound cannot be found, do not play the system default sound.

winsound.SND_NOSTOP

Do not interrupt sounds currently playing.

winsound.SND_NOWAIT

Return immediately if the sound driver is busy.

Note

This flag is not supported on modern Windows platforms.

winsound.MB_ICONASTERISK

Play the `SystemDefault` sound.

winsound.MB_ICONEXCLAMATION
: Play the `SystemExclamation` sound.

winsound.MB_ICONHAND
: Play the `SystemHand` sound.

winsound.MB_ICONQUESTION
: Play the `SystemQuestion` sound.

winsound.MB_OK
: Play the `SystemDefault` sound.

Unix Specific Services

The modules described in this chapter provide interfaces to features that are unique to the Unix operating system, or in some cases to some or many variants of it. Here's an overview:

- **`posix`** — The most common POSIX system calls
  - Large File Support
  - Notable Module Contents
- **`pwd`** — The password database
- **`grp`** — The group database
- **`termios`** — POSIX style tty control
  - Example
- **`tty`** — Terminal control functions
- **`pty`** — Pseudo-terminal utilities
  - Example
- **`fcntl`** — The **`fcntl`** and **`ioctl`** system calls
- **`resource`** — Resource usage information
  - Resource Limits
  - Resource Usage
- **`syslog`** — Unix syslog library routines
  - Examples
    - Simple example

`posix` — The most common POSIX system calls

This module provides access to operating system functionality that is standardized by the C Standard and the POSIX standard (a thinly disguised Unix interface).

Do not import this module directly. Instead, import the module `os`, which provides a *portable* version of this interface. On Unix, the `os` module provides a superset of the `posix` interface. On non-Unix operating systems the `posix` module is not available, but a subset is always available through the `os` interface. Once `os` is imported, there is *no* performance penalty in using it instead of `posix`. In addition, `os` provides some additional functionality, such as automatically calling `putenv()` when an entry in `os.environ` is changed.

Errors are reported as exceptions; the usual exceptions are given for type errors, while errors reported by the system calls raise `OSError`.

Large File Support

Several operating systems (including AIX and Solaris) provide support for files that are larger than 2 GiB from a C programming model where int and long are 32-bit values. This is typically accomplished by defining the relevant size and offset types as 64-bit values. Such files are sometimes referred to as *large files*.

Large file support is enabled in Python when the size of an `off_t` is larger than a long and the long long is at least as large as an `off_t`. It may be necessary to configure and compile Python with certain compiler flags to enable this mode. For example, with Solaris 2.6 and 2.7 you need to do something like:

```
CFLAGS="`getconf LFS_CFLAGS`" OPT="-g -O2 $CFLAGS" \
        ./configure
```

On large-file-capable Linux systems, this might work:

```
CFLAGS='-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64' OP
        ./configure
```

Notable Module Contents

In addition to many functions described in the **os** module documentation, **posix** defines the following data item:

posix.environ

A dictionary representing the string environment at the time the interpreter was started. Keys and values are bytes on Unix and str on Windows. For example, `environ[b'HOME']` (`environ['HOME']` on Windows) is the pathname of your home directory, equivalent to `getenv("HOME")` in C.

Modifying this dictionary does not affect the string environment passed on by **execv()**, **popen()** or **system()**; if you need to change the environment, pass `environ` to **execve()** or add variable assignments and export statements to the command string for **system()** or **popen()**.

Changed in version 3.2: On Unix, keys and values are bytes.

Note

The **os** module provides an alternate implementation of `environ` which updates the environment on modification. Note also that updating **os.environ** will render this dictionary obsolete. Use of the **os** module version of this is recommended over direct access to the **posix** module.

pwd — The password database

This module provides access to the Unix user account and password database. It is available on all Unix versions.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `passwd` structure (Attribute field below, see `<pwd.h>`):

Index	Attribute	Meaning
0	pw_name	Login name
1	pw_passwd	Optional encrypted password
2	pw_uid	Numerical user ID
3	pw_gid	Numerical group ID
4	pw_gecos	User name or comment field
5	pw_dir	User home directory
6	pw_shell	User command interpreter

The uid and gid items are integers, all others are strings. **KeyError** is raised if the entry asked for cannot be found.

Note

In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm (see module **crypt**). However most modern unices use a so-called *shadow password* system. On those unices the *pw_passwd* field only contains an asterisk (`'*'`) or the letter `'x'` where the encrypted password is stored in a file `/etc/shadow` which is not world

readable. Whether the *pw_passwd* field contains anything useful is system-dependent. If available, the **spwd** module should be used where access to the encrypted password is required.

It defines the following items:

pwd.getpwuid(*uid*)
: Return the password database entry for the given numeric user ID.

pwd.getpwnam(*name*)
: Return the password database entry for the given user name.

pwd.getpwall()
: Return a list of all available password database entries, in arbitrary order.

See also

Module **grp**
: An interface to the group database, similar to this.

Module **spwd**
: An interface to the shadow password database, similar to this.

grp — The group database

This module provides access to the Unix group database. It is available on all Unix versions.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the `group` structure (Attribute field below, see `<grp.h>`):

Index	Attribute	Meaning
0	gr_name	the name of the group
1	gr_passwd	the (encrypted) group password; often empty
2	gr_gid	the numerical group ID
3	gr_mem	all the group member's user names

The gid is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a `+` or `-` is likely to be a YP/NIS reference and may not be accessible via **`getgrnam()`** or **`getgrgid()`**.)

It defines the following items:

grp.getgrgid(*id*)

Return the group database entry for the given numeric group ID. **`KeyError`** is raised if the entry asked for cannot be found.

Changed in version 3.10: **TypeError** is raised for non-integer arguments like floats or strings.

grp.getgrnam(*name*)

Return the group database entry for the given group name. **KeyError** is raised if the entry asked for cannot be found.

grp.getgrall()

Return a list of all available group entries, in arbitrary order.

Module pwd
An interface to the user database, similar to this.

Module spwd
An interface to the shadow password database, similar to this.

`termios` — POSIX style tty control

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see *termios(3)* Unix manual page. It is only available for those Unix versions that support POSIX *termios* style tty I/O control configured during installation.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a file object, such as `sys.stdin` itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

termios.tcgetattr(*fd*)

Return a list containing the tty attributes for file descriptor *fd*, as follows: `[iflag, oflag, cflag, lflag, ispeed, ospeed, cc]` where *cc* is a list of the tty special characters (each a string of length 1, except the items with indices **`VMIN`** and **`VTIME`**, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the *cc* array must be done using the symbolic constants defined in the `termios` module.

termios.tcsetattr(*fd*, *when*, *attributes*)

Set the tty attributes for file descriptor *fd* from the *attributes*, which is a list like the one returned by `tcgetattr()`. The *when* argument determines when the attributes are changed:

TCSANOW to change immediately, **TCSADRAIN** to change after transmitting all queued output, or **TCSAFLUSH** to change after transmitting all queued output and discarding all queued input.

termios.tcsendbreak(*fd*, *duration*)

Send a break on file descriptor *fd*. A zero *duration* sends a break for 0.25–0.5 seconds; a nonzero *duration* has a system dependent meaning.

termios.tcdrain(*fd*)

Wait until all output written to file descriptor *fd* has been transmitted.

termios.tcflush(*fd*, *queue*)

Discard queued data on file descriptor *fd*. The *queue* selector specifies which queue: **TCIFLUSH** for the input queue, **TCOFLUSH** for the output queue, or **TCIOFLUSH** for both queues.

termios.tcflow(*fd*, *action*)

Suspend or resume input or output on file descriptor *fd*. The *action* argument can be **TCOOFF** to suspend output, **TCOON** to restart output, **TCIOFF** to suspend input, or **TCION** to restart input.

termios.tcgetwinsize(*fd*)

Return a tuple `(ws_row, ws_col)` containing the tty window size for file descriptor *fd*. Requires **termios.TIOCGWINSZ** or **termios.TIOCGSIZE**.

New in version 3.11.

termios.tcsetwinsize(*fd*, *winsize*)

Set the tty window size for file descriptor *fd* from *winsize*, which is a two-item tuple `(ws_row, ws_col)` like the one returned by **tcgetwinsize()**. Requires at least one of the

pairs (**termios.TIOCGWINSZ**, **termios.TIOCSWINSZ**); (**termios.TIOCGSIZE**, **termios.TIOCSSIZE**) to be defined.

New in version 3.11.

See also

Module **tty**
Convenience functions for common terminal control operations.

Example

Here's a function that prompts for a password with echoing turned off. Note the technique using a separate **tcgetattr()** call and a **try** … **finally** statement to ensure that the old tty attributes are restored exactly no matter what happens:

```
def getpass(prompt="Password: "):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)
    new[3] = new[3] & ~termios.ECHO          # lflags
    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)
    return passwd
```

`tty` — Terminal control functions

Source code: Lib/tty.py [https://github.com/python/cpython/tree/3.11/Lib/tty.py]

The `tty` module defines functions for putting the tty into cbreak and raw modes.

Because it requires the `termios` module, it will work only on Unix.

The `tty` module defines the following functions:

tty.setraw(*fd*, *when*=*termios.TCSAFLUSH*)

Change the mode of the file descriptor *fd* to raw. If *when* is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

tty.setcbreak(*fd*, *when*=*termios.TCSAFLUSH*)

Change the mode of file descriptor *fd* to cbreak. If *when* is omitted, it defaults to `termios.TCSAFLUSH`, and is passed to `termios.tcsetattr()`.

See also

Module `termios`

Low-level terminal control interface.

`pty` — Pseudo-terminal utilities

Source code: Lib/pty.py [https://github.com/python/cpython/tree/3.11/Lib/pty.py]

The `pty` module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programmatically.

Pseudo-terminal handling is highly platform dependent. This code is mainly tested on Linux, FreeBSD, and macOS (it is supposed to work on other POSIX platforms but it's not been thoroughly tested).

The `pty` module defines the following functions:

pty.fork()

Fork. Connect the child's controlling terminal to a pseudo-terminal. Return value is `(pid, fd)`. Note that the child gets *pid* 0, and the *fd* is *invalid*. The parent's return value is the *pid* of the child, and *fd* is a file descriptor connected to the child's controlling terminal (and also to the child's standard input and output).

pty.openpty()

Open a new pseudo-terminal pair, using `os.openpty()` if possible, or emulation code for generic Unix systems. Return a pair of file descriptors `(master, slave)`, for the master and the slave end, respectively.

pty.spawn(*argv*[, *master_read*[, *stdin_read*]])

Spawn a process, and connect its controlling terminal with the current process's standard io. This is often used to baffle programs which insist on reading from the controlling terminal. It is expected that the process spawned behind the

pty will eventually terminate, and when it does *spawn* will return.

A loop copies STDIN of the current process to the child and data received from the child to STDOUT of the current process. It is not signaled to the child if STDIN of the current process closes down.

The functions *master_read* and *stdin_read* are passed a file descriptor which they should read from, and they should always return a byte string. In order to force spawn to return before the child process exits an empty byte array should be returned to signal end of file.

The default implementation for both functions will read and return up to 1024 bytes each time the function is called. The *master_read* callback is passed the pseudoterminal's master file descriptor to read output from the child process, and *stdin_read* is passed file descriptor 0, to read from the parent process's standard input.

Returning an empty byte string from either callback is interpreted as an end-of-file (EOF) condition, and that callback will not be called after that. If *stdin_read* signals EOF the controlling terminal can no longer communicate with the parent process OR the child process. Unless the child process will quit without any input, *spawn* will then loop forever. If *master_read* signals EOF the same behavior results (on linux at least).

Return the exit status value from **`os.waitpid()`** on the child process.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

Raises an auditing event `pty.spawn` with argument `argv`.

Changed in version 3.4: **`spawn()`** now returns the status value from **`os.waitpid()`** on the child process.

Example

The following program acts like the Unix command *script(1)*, using a pseudo-terminal to record all input and output of a terminal session in a “typescript”.

```
import argparse
import os
import pty
import sys
import time

parser = argparse.ArgumentParser()
parser.add_argument('-a', dest='append', action='store_t
parser.add_argument('-p', dest='use_python', action='sto
parser.add_argument('filename', nargs='?', default='type
options = parser.parse_args()

shell = sys.executable if options.use_python else os.env
filename = options.filename
mode = 'ab' if options.append else 'wb'

with open(filename, mode) as script:
    def read(fd):
        data = os.read(fd, 1024)
        script.write(data)
        return data

    print('Script started, file is', filename)
    script.write(('Script started on %s\n' % time.asctim

    pty.spawn(shell, read)

    script.write(('Script done on %s\n' % time.asctime()
    print('Script done, file is', filename)
```

`fcntl` — The `fcntl` and `ioctl` system calls

This module performs file control and I/O control on file descriptors. It is an interface to the **`fcntl()`** and **`ioctl()`** Unix routines. For a complete description of these calls, see *fcntl(2)* and *ioctl(2)* Unix manual pages.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or an **`io.IOBase`** object, such as `sys.stdin` itself, which provides a **`fileno()`** that returns a genuine file descriptor.

Changed in version 3.3: Operations in this module used to raise an **`IOError`** where they now raise an **`OSError`**.

Changed in version 3.8: The fcntl module now contains `F_ADD_SEALS`, `F_GET_SEALS`, and `F_SEAL_*` constants for sealing of **`os.memfd_create()`** file descriptors.

Changed in version 3.9: On macOS, the fcntl module exposes the `F_GETPATH` constant, which obtains the path of a file from a file descriptor. On Linux(>=3.15), the fcntl module exposes the `F_OFD_GETLK`, `F_OFD_SETLK` and `F_OFD_SETLKW` constants, which are used when working with open file description locks.

Changed in version 3.10: On Linux >= 2.6.11, the fcntl module

exposes the `F_GETPIPE_SZ` and `F_SETPIPE_SZ` constants, which allow to check and modify a pipe's size respectively.

Changed in version 3.11: On FreeBSD, the fcntl module exposes the `F_DUP2FD` and `F_DUP2FD_CLOEXEC` constants, which allow to duplicate a file descriptor, the latter setting `FD_CLOEXEC` flag in addition.

The module defines the following functions:

fcntl.fcntl(*fd*, *cmd*, *arg=0*)

Perform the operation *cmd* on file descriptor *fd* (file objects providing a **`fileno()`** method are accepted as well). The values used for *cmd* are operating system dependent, and are available as constants in the **`fcntl`** module, using the same names as used in the relevant C header files. The argument *arg* can either be an integer value, or a **`bytes`** object. With an integer value, the return value of this function is the integer return value of the C **`fcntl()`** call. When the argument is bytes it represents a binary structure, e.g. created by **`struct.pack()`**. The binary data is copied to a buffer whose address is passed to the C **`fcntl()`** call. The return value after a successful call is the contents of the buffer, converted to a **`bytes`** object. The length of the returned object will be the same as the length of the *arg* argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption.

If the **`fcntl()`** fails, an **`OSError`** is raised.

Raises an auditing event `fcntl.fcntl` with arguments `fd`, `cmd`, `arg`.

fcntl.ioctl(*fd*, *request*, *arg=0*, *mutate_flag=True*)

This function is identical to the **`fcntl()`** function, except that the argument handling is even more complicated.

The *request* parameter is limited to values that can fit in 32-

bits. Additional constants of interest for use as the *request* argument can be found in the **termios** module, under the same names as used in the relevant C header files.

The parameter *arg* can be one of an integer, an object supporting the read-only buffer interface (like **bytes**) or an object supporting the read-write buffer interface (like **bytearray**).

In all but the last case, behaviour is as for the **fcntl()** function.

If a mutable buffer is passed, then the behaviour is determined by the value of the *mutate_flag* parameter.

If it is false, the buffer's mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided – so long as the buffer you pass is at least as long as what the operating system wants to put there, things should work.

If *mutate_flag* is true (the default), then the buffer is (in effect) passed to the underlying **ioctl()** system call, the latter's return code is passed back to the calling Python, and the buffer's new contents reflect the action of the **ioctl()**. This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first copied into a static buffer 1024 bytes long which is then passed to **ioctl()** and copied back into the supplied buffer.

If the **ioctl()** fails, an **OSError** exception is raised.

An example:

```
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCG
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPGRP, buf, 1)
```

```
0
>>> buf
array('h', [13341])
```

Raises an auditing event `fcntl.ioctl` with arguments `fd`, `request`, `arg`.

fcntl.flock(*fd*, *operation*)

Perform the lock operation *operation* on file descriptor *fd* (file objects providing a **`fileno()`** method are accepted as well). See the Unix manual *flock(2)* for details. (On some systems, this function is emulated using **`fcntl()`**.)

If the **`flock()`** fails, an **`OSError`** exception is raised.

Raises an auditing event `fcntl.flock` with arguments `fd`, `operation`.

fcntl.lockf(*fd*, *cmd*, *len=0*, *start=0*, *whence=0*)

This is essentially a wrapper around the **`fcntl()`** locking calls. *fd* is the file descriptor (file objects providing a **`fileno()`** method are accepted as well) of the file to lock or unlock, and *cmd* is one of the following values:

- **`LOCK_UN`** – unlock
- **`LOCK_SH`** – acquire a shared lock
- **`LOCK_EX`** – acquire an exclusive lock

When *cmd* is **`LOCK_SH`** or **`LOCK_EX`**, it can also be bitwise ORed with **`LOCK_NB`** to avoid blocking on lock acquisition. If **`LOCK_NB`** is used and the lock cannot be acquired, an **`OSError`** will be raised and the exception will have an *errno* attribute set to **`EACCES`** or **`EAGAIN`** (depending on the operating system; for portability, check for both values). On at least some systems, **`LOCK_EX`** can only be used if the file descriptor refers to a file opened for writing.

len is the number of bytes to lock, *start* is the byte offset at which the lock starts, relative to *whence*, and *whence* is as with **`io.IOBase.seek()`**, specifically:

- **0** – relative to the start of the file (**os.SEEK_SET**)
- **1** – relative to the current buffer position (**os.SEEK_CUR**)
- **2** – relative to the end of the file (**os.SEEK_END**)

The default for *start* is 0, which means to start at the beginning of the file. The default for *len* is 0 which means to lock to the end of the file. The default for *whence* is also 0.

Raises an auditing event `fcntl.lockf` with arguments `fd`, `cmd`, `len`, `start`, `whence`.

Examples (all on a SVR4 compliant system):

```
import struct, fcntl, os

f = open(...)
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)

lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0,
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable *rv* will hold an integer value; in the second example it will hold a **bytes** object. The structure lay-out for the *lockdata* variable is system dependent — therefore using the **flock()** call may be better.

See also

Module os

If the locking flags **O_SHLOCK** and **O_EXLOCK** are present in the **os** module (on BSD only), the **os.open()** function provides an alternative to the **lockf()** and **flock()** functions.

`resource` — Resource usage information

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

An `OSError` is raised on syscall failure.

exception resource.error

A deprecated alias of `OSError`.

Changed in version 3.3: Following **PEP 3151** [https://peps.python.org/pep-3151/], this class was made an alias of `OSError`.

Resource Limits

Resources usage can be limited using the `setrlimit()` function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes

with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the *getrlimit(2)* man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

resource.RLIM_INFINITY

Constant used to represent the limit for an unlimited resource.

resource.getrlimit(*resource*)

Returns a tuple `(soft, hard)` with the current soft and hard limits of *resource*. Raises **`ValueError`** if an invalid resource is specified, or **`error`** if the underlying system call fails unexpectedly.

resource.setrlimit(*resource*, *limits*)

Sets new limits of consumption of *resource*. The *limits* argument must be a tuple `(soft, hard)` of two integers describing the new limits. A value of **`RLIM_INFINITY`** can be used to request a limit that is unlimited.

Raises **`ValueError`** if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its hard limit. Specifying a limit of **`RLIM_INFINITY`** when the hard or system limit for that resource is not unlimited will result in a **`ValueError`**. A process with the effective UID of super-user can request any valid limit value, including unlimited, but **`ValueError`** will still be raised if the requested limit exceeds the system imposed limit.

`setrlimit` may also raise **`error`** if the underlying system call fails.

VxWorks only supports setting **`RLIMIT_NOFILE`**.

Raises an auditing event `resource.setrlimit` with

arguments `resource, limits`.

resource.prlimit(*pid*, *resource*[, *limits*])

Combines **`setrlimit()`** and **`getrlimit()`** in one function and supports to get and set the resources limits of an arbitrary process. If *pid* is 0, then the call applies to the current process. *resource* and *limits* have the same meaning as in **`setrlimit()`**, except that *limits* is optional.

When *limits* is not given the function returns the *resource* limit of the process *pid*. When *limits* is given the *resource* limit of the process is set and the former resource limit is returned.

Raises **`ProcessLookupError`** when *pid* can't be found and **`PermissionError`** when the user doesn't have `CAP_SYS_RESOURCE` for the process.

Raises an auditing event `resource.prlimit` with arguments `pid, resource, limits`.

Availability: Linux >= 2.6.36 with glibc >= 2.13.

New in version 3.4.

These symbols define resources whose consumption can be controlled using the **`setrlimit()`** and **`getrlimit()`** functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for *getrlimit(2)* lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences — symbols not defined for a platform will not be available from this module on that platform.

resource.RLIMIT_CORE

The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

resource.RLIMIT_CPU

The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a **SIGXCPU** signal is sent to the process. (See the **signal** module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

resource.RLIMIT_FSIZE

The maximum size of a file which the process may create.

resource.RLIMIT_DATA

The maximum size (in bytes) of the process's heap.

resource.RLIMIT_STACK

The maximum size (in bytes) of the call stack for the current process. This only affects the stack of the main thread in a multi-threaded process.

resource.RLIMIT_RSS

The maximum resident set size that should be made available to the process.

resource.RLIMIT_NPROC

The maximum number of processes the current process may create.

resource.RLIMIT_NOFILE

The maximum number of open file descriptors for the current process.

resource.RLIMIT_OFILE

The BSD name for **RLIMIT_NOFILE**.

resource.RLIMIT_MEMLOCK

The maximum address space which may be locked in memory.

resource.RLIMIT_VMEM

The largest area of mapped memory which the process may occupy.

resource.RLIMIT_AS

The maximum area (in bytes) of address space which may be taken by the process.

resource.RLIMIT_MSGQUEUE

The number of bytes that can be allocated for POSIX message queues.

Availability: Linux >= 2.6.8.

New in version 3.4.

resource.RLIMIT_NICE

The ceiling for the process's nice level (calculated as 20 - rlim_cur).

Availability: Linux >= 2.6.12.

New in version 3.4.

resource.RLIMIT_RTPRIO

The ceiling of the real-time priority.

Availability: Linux >= 2.6.12.

New in version 3.4.

resource.RLIMIT_RTTIME

The time limit (in microseconds) on CPU time that a process can spend under real-time scheduling without making a blocking syscall.

Availability: Linux >= 2.6.25.

New in version 3.4.

resource.RLIMIT_SIGPENDING

The number of signals which the process may queue.

Availability: Linux >= 2.6.8.

New in version 3.4.

resource.RLIMIT_SBSIZE

The maximum size (in bytes) of socket buffer usage for this user. This limits the amount of network memory, and hence the amount of mbufs, that this user may hold at any time.

Availability: FreeBSD.

New in version 3.4.

resource.RLIMIT_SWAP

The maximum size (in bytes) of the swap space that may be reserved or used by all of this user id's processes. This limit is enforced only if bit 1 of the vm.overcommit sysctl is set. Please see tuning(7) [https://www.freebsd.org/cgi/man.cgi?query=tuning&sektion=7] for a complete description of this sysctl.

Availability: FreeBSD.

New in version 3.4.

resource.RLIMIT_NPTS

The maximum number of pseudo-terminals created by this user id.

Availability: FreeBSD.

New in version 3.4.

resource.RLIMIT_KQUEUES

The maximum number of kqueues this user id is allowed to create.

Availability: FreeBSD >= 11.

New in version 3.10.

Resource Usage

These functions are used to retrieve resource usage information:

resource.getrusage(*who*)

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the *who* parameter. The *who* parameter should be specified using one of the **RUSAGE_*** constants described below.

A simple example:

```
from resource import *
import time

# a non CPU-bound task
time.sleep(3)
print(getrusage(RUSAGE_SELF))

# a CPU-bound task
for i in range(10 ** 8):
    _ = 1 + 1
print(getrusage(RUSAGE_SELF))
```

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running is user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick internal, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields **ru_utime** and **ru_stime** of the return value are

floating point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the *getrusage(2)* man page for detailed information about these values. A brief summary is presented here:

Index	Field	Resource
0	ru_utime	time in user mode (float seconds)
1	ru_stime	time in system mode (float seconds)
2	ru_maxrss	maximum resident set size
3	ru_ixrss	shared memory size
4	ru_idrss	unshared memory size
5	ru_isrss	unshared stack size
6	ru_minflt	page faults not requiring I/O
7	ru_majflt	page faults requiring I/O
8	ru_nswap	number of swap outs
9	ru_inblock	block input operations
10	ru_oublock	block output operations
11	ru_msgsnd	messages sent
12	ru_msgrcv	messages received
13	ru_nsignals	signals received
14	ru_nvcsw	voluntary context switches
15	ru_nivcsw	involuntary context switches

This function will raise a **ValueError** if an invalid *who* parameter is specified. It may also raise **error** exception in unusual circumstances.

resource.getpagesize()

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.)

The following **RUSAGE_*** symbols are passed to the **getrusage()** function to specify which processes information should be provided for.

resource.RUSAGE_SELF

Pass to **getrusage()** to request resources consumed by the calling process, which is the sum of resources used by all

threads in the process.

resource.RUSAGE_CHILDREN

Pass to `getrusage()` to request resources consumed by child processes of the calling process which have been terminated and waited for.

resource.RUSAGE_BOTH

Pass to `getrusage()` to request resources consumed by both the current process and child processes. May not be available on all systems.

resource.RUSAGE_THREAD

Pass to `getrusage()` to request resources consumed by the current thread. May not be available on all systems.

New in version 3.2.

`syslog` — Unix syslog library routines

This module provides an interface to the Unix `syslog` library routines. Refer to the Unix manual pages for a detailed description of the `syslog` facility.

This module wraps the system `syslog` family of routines. A pure Python library that can speak to a syslog server is available in the `logging.handlers` module as **`SysLogHandler`**.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The module defines the following functions:

syslog.syslog(*message*)
syslog.syslog(*priority*, *message*)

Send the string *message* to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a *facility* and a *level*. The optional *priority* argument, which defaults to **`LOG_INFO`**, determines the message priority. If the facility is not encoded in *priority* using logical-or (`LOG_INFO | LOG_USER`), the value given in the `openlog()` call is used.

If `openlog()` has not been called prior to the call to `syslog()`, `openlog()` will be called with no arguments.

Raises an auditing event `syslog.syslog` with arguments `priority`, `message`.

Changed in version 3.2: In previous versions, **`openlog()`** would not be called automatically if it wasn't called prior to the call to **`syslog()`**, deferring to the syslog implementation to call `openlog()`.

syslog.openlog([*ident*[, *logoption*[, *facility*]]])

Logging options of subsequent **`syslog()`** calls can be set by calling **`openlog()`**. **`syslog()`** will call **`openlog()`** with no arguments if the log is not currently open.

The optional *ident* keyword argument is a string which is prepended to every message, and defaults to `sys.argv[0]` with leading path components stripped. The optional *logoption* keyword argument (default is 0) is a bit field – see below for possible values to combine. The optional *facility* keyword argument (default is **`LOG_USER`**) sets the default facility for messages which do not have a facility explicitly encoded.

Raises an auditing event `syslog.openlog` with arguments `ident, logoption, facility`.

Changed in version 3.2: In previous versions, keyword arguments were not allowed, and *ident* was required.

syslog.closelog()

Reset the syslog module values and call the system library `closelog()`.

This causes the module to behave as it does when initially imported. For example, **`openlog()`** will be called on the first **`syslog()`** call (if **`openlog()`** hasn't already been called), and *ident* and other **`openlog()`** parameters are reset to defaults.

Raises an auditing event `syslog.closelog` with no arguments.

syslog.setlogmask(*maskpri*)

Set the priority mask to *maskpri* and return the previous mask

value. Calls to **`syslog()`** with a priority level not set in *maskpri* are ignored. The default is to log all priorities. The function `LOG_MASK(pri)` calculates the mask for the individual priority *pri*. The function `LOG_UPTO(pri)` calculates the mask for all priorities up to and including *pri*.

Raises an auditing event `syslog.setlogmask` with argument `maskpri`.

The module defines the following constants:

Priority levels (high to low):
`LOG_EMERG`, **`LOG_ALERT`**, **`LOG_CRIT`**, **`LOG_ERR`**, **`LOG_WARNING`**, **`LOG_NOTICE`**, **`LOG_INFO`**, **`LOG_DEBUG`**.

Facilities:
`LOG_KERN`, **`LOG_USER`**, **`LOG_MAIL`**, **`LOG_DAEMON`**, **`LOG_AUTH`**, **`LOG_LPR`**, **`LOG_NEWS`**, **`LOG_UUCP`**, **`LOG_CRON`**, **`LOG_SYSLOG`**, **`LOG_LOCAL0`** to **`LOG_LOCAL7`**, and, if defined in `<syslog.h>`, **`LOG_AUTHPRIV`**.

Log options:
`LOG_PID`, **`LOG_CONS`**, **`LOG_NDELAY`**, and, if defined in `<syslog.h>`, **`LOG_ODELAY`**, **`LOG_NOWAIT`**, and **`LOG_PERROR`**.

Examples

Simple example

A simple set of examples:

```
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the

destination facility used for mail logging:

```
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog
syslog.syslog('E-mail processing initiated...')
```

Superseded Modules

The modules described in this chapter are deprecated and only kept for backwards compatibility. They have been superseded by other modules.

- **aifc** — Read and write AIFF and AIFC files
- **asynchat** — Asynchronous socket command/response handler
    - asynchat Example
- **asyncore** — Asynchronous socket handler
    - asyncore Example basic HTTP client
    - asyncore Example basic echo server

    - Unpacker Objects
    - Exceptions

`aifc` — Read and write AIFF and AIFC files

Source code: Lib/aifc.py [https://github.com/python/cpython/tree/3.11/Lib/aifc.py]

Deprecated since version 3.11, will be removed in version 3.13: The `aifc` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#aifc] for details).

This module provides support for reading and writing AIFF and AIFF-C files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of `nchannels * samplesize` bytes, and a second's worth of audio consists of `nchannels * samplesize * framerate` bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes (2*2), and a second's worth occupies 2*2*44100 bytes (176,400 bytes).

Module `aifc` defines the following function:

aifc.open(*file*, *mode*=*None*)

Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument *file* is either a string naming a file or a file object. *mode* must be

`'r'` or `'rb'` when the file must be opened for reading, or `'w'` or `'wb'` when the file must be opened for writing. If omitted, `file.mode` is used if it exists, otherwise `'rb'` is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use **`writeframesraw()`** and **`setnframes()`**. The **`open()`** function may be used in a **`with`** statement. When the **`with`** block completes, the **`close()`** method is called.

Changed in version 3.4: Support for the **`with`** statement was added.

Objects returned by **`open()`** when a file is opened for reading have the following methods:

aifc.getnchannels()

Return the number of audio channels (1 for mono, 2 for stereo).

aifc.getsampwidth()

Return the size in bytes of individual samples.

aifc.getframerate()

Return the sampling rate (number of audio frames per second).

aifc.getnframes()

Return the number of audio frames in the file.

aifc.getcomptype()

Return a bytes array of length 4 describing the type of compression used in the audio file. For AIFF files, the returned value is `b'NONE'`.

aifc.getcompname()

Return a bytes array convertible to a human-readable

description of the type of compression used in the audio file. For AIFF files, the returned value is `b'not compressed'`.

aifc.getparams()

Returns a **`namedtuple()`** `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, equivalent to output of the **`get*()`** methods.

aifc.getmarkers()

Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

aifc.getmark(*id*)

Return the tuple as described in **`getmarkers()`** for the mark with the given *id*.

aifc.readframes(*nframes*)

Read and return the next *nframes* frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

aifc.rewind()

Rewind the read pointer. The next **`readframes()`** will start from the beginning.

aifc.setpos(*pos*)

Seek to the specified frame number.

aifc.tell()

Return the current frame number.

aifc.close()

Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by **`open()`** when a file is opened for writing have all the above methods, except for **`readframes()`** and **`setpos()`**. In addition the following methods exist. The **`get*()`** methods can only be called after the corresponding **`set*()`** methods have been called. Before the first **`writeframes()`** or **`writeframesraw()`**, all parameters except for the number of frames must be filled in.

aifc.aiff()

Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in `'.aiff'` in which case the default is an AIFF file.

aifc.aifc()

Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in `'.aiff'` in which case the default is an AIFF file.

aifc.setnchannels(*nchannels*)

Specify the number of channels in the audio file.

aifc.setsampwidth(*width*)

Specify the size in bytes of audio samples.

aifc.setframerate(*rate*)

Specify the sampling frequency in frames per second.

aifc.setnframes(*nframes*)

Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

aifc.setcomptype(*type*, *name*)

Specify the compression type. If not specified, the audio data

will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type as a bytes array, the type parameter should be a bytes array of length 4. Currently the following compression types are supported: `b'NONE'`, `b'ULAW'`, `b'ALAW'`, `b'G722'`.

aifc.setparams(*nchannels*, *sampwidth*, *framerate*, *comptype*, *compname*)

Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a **`getparams()`** call as argument to **`setparams()`**.

aifc.setmark(*id*, *pos*, *name*)

Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before **`close()`**.

aifc.tell()

Return the current write position in the output file. Useful in combination with **`setmark()`**.

aifc.writeframes(*data*)

Write data to the output file. This method can only be called after the audio file parameters have been set.

Changed in version 3.4: Any bytes-like object is now accepted.

aifc.writeframesraw(*data*)

Like **`writeframes()`**, except that the header of the audio file is not updated.

Changed in version 3.4: Any bytes-like object is now accepted.

aifc.close()

Close the AIFF file. The header of the file is updated to reflect

the actual size of the audio data. After calling this method, the object can no longer be used.

`asynchat` — Asynchronous socket command/response handler

Source code: Lib/asynchat.py [https://github.com/python/cpython/tree/3.11/Lib/asynchat.py]

Deprecated since version 3.6, will be removed in version 3.12: The `asynchat` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#asynchat] for details). Please use `asyncio` instead.

Note

This module exists for backwards compatibility only. For new code we recommend using `asyncio`.

This module builds on the `asyncore` infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. `asynchat` defines the abstract class `async_chat` that you subclass, providing implementations of the `collect_incoming_data()` and `found_terminator()` methods. It uses the same asynchronous loop as `asyncore`, and the two types of channel, `asyncore.dispatcher` and `asynchat.async_chat`, can freely be mixed in the channel map. Typically an `asyncore.dispatcher` server channel generates new `asynchat.async_chat` channel objects as it receives incoming connection requests.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See

WebAssembly platforms for more information.

class asynchat.async_chat

This class is an abstract subclass of **asyncore.dispatcher**. To make practical use of the code you must subclass **async_chat**, providing meaningful **collect_incoming_data()** and **found_terminator()** methods. The **asyncore.dispatcher** methods can be used, although not all make sense in a message/response context.

Like **asyncore.dispatcher**, **async_chat** defines a set of events that are generated by an analysis of socket conditions after a **select()** call. Once the polling loop has been started the **async_chat** object's methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.

ac_in_buffer_size

The asynchronous input buffer size (default `4096`).

ac_out_buffer_size

The asynchronous output buffer size (default `4096`).

Unlike **asyncore.dispatcher**, **async_chat** allows you to define a FIFO queue of *producers*. A producer need have only one method, **more()**, which should return data to be transmitted on the channel. The producer indicates exhaustion (*i.e.* that it contains no more data) by having its **more()** method return the empty bytes object. At this point the **async_chat** object removes the producer from the queue and starts using the next producer, if any. When the producer queue is empty the **handle_write()** method does nothing. You use the channel object's **set_terminator()** method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the

remote endpoint.

To build a functioning **async_chat** subclass your input methods **collect_incoming_data()** and **found_terminator()** must handle the data that the channel receives asynchronously. The methods are described below.

async_chat.close_when_done()

Pushes a `None` on to the producer queue. When this producer is popped off the queue it causes the channel to be closed.

async_chat.collect_incoming_data(*data*)

Called with *data* holding an arbitrary amount of received data. The default method, which must be overridden, raises a **NotImplementedError** exception.

async_chat.discard_buffers()

In emergencies this method will discard any data held in the input and/or output buffers and the producer queue.

async_chat.found_terminator()

Called when the incoming data stream matches the termination condition set by **set_terminator()**. The default method, which must be overridden, raises a **NotImplementedError** exception. The buffered input data should be available via an instance attribute.

async_chat.get_terminator()

Returns the current terminator for the channel.

async_chat.push(*data*)

Pushes data on to the channel's queue to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.

async_chat.push_with_producer(*producer*)

Takes a producer object and adds it to the producer queue associated with the channel. When all currently pushed producers have been exhausted the channel will consume this producer's data by calling its **`more()`** method and send the data to the remote endpoint.

async_chat.set_terminator(*term*)

Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

Term	Description
string	Will call **`found_terminator()`** when the string is found in the input stream
integer	Will call **`found_terminator()`** when the indicated number of characters have been received
`None`	The channel continues to collect data forever

Note that any data following the terminator will be available for reading by the channel after **`found_terminator()`** is called.

asynchat Example

The following partial example shows how HTTP requests can be read with **`async_chat`**. A web server might create an **`http_request_handler`** object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the `Content-Length:` header is used to set a numeric terminator to read the right amount of data from the channel.

The **`handle_request()`** method is called once all relevant input

has been marshalled, after setting the channel terminator to `None` to ensure that any extraneous data sent by the web client are ignored.

```
import asynchat

class http_request_handler(asynchat.async_chat):

    def __init__(self, sock, addr, sessions, log):
        asynchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = b""
        self.set_terminator(b"\r\n\r\n")
        self.reading_headers = True
        self.handling = False
        self.cgi_data = None
        self.log = log

    def collect_incoming_data(self, data):
        """Buffer the data"""
        self.ibuffer.append(data)

    def found_terminator(self):
        if self.reading_headers:
            self.reading_headers = False
            self.parse_headers(b"".join(self.ibuffer))
            self.ibuffer = []
            if self.op.upper() == b"POST":
                clen = self.headers.getheader("content-l
                self.set_terminator(int(clen))
            else:
                self.handling = True
                self.set_terminator(None)
                self.handle_request()
        elif not self.handling:
            self.set_terminator(None)  # browsers someti
            self.cgi_data = parse(self.headers, b"".join
```

```
        self.handling = True
        self.ibuffer = []
        self.handle_request()
```

`asyncore` — Asynchronous socket handler

Source code: Lib/asyncore.py [https://github.com/python/cpython/tree/3.11/Lib/asyncore.py]

Deprecated since version 3.6, will be removed in version 3.12: The `asyncore` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#asyncore] for details). Please use `asyncio` instead.

Note

This module exists for backwards compatibility only. For new code we recommend using `asyncio`.

This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

There are only two ways to have a program on a single processor do "more than one thing at a time." Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It's really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the **select()** system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the "background." Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The **asyncore** module solves many of the difficult problems for you, making the task of building sophisticated high-performance network servers and clients a snap. For "conversational" applications and protocols the companion **asynchat** module is invaluable.

The basic idea behind both modules is to create one or more network *channels*, instances of class **asyncore.dispatcher** and **asynchat.async_chat**. Creating the channels adds them to a global map, used by the **loop()** function if you do not provide it with your own *map*.

Once the initial channel(s) is(are) created, calling the **loop()** function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

asyncore.loop([*timeout*[, *use_poll*[, *map*[, *count*]]]])

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The *count* parameter defaults to `None`, resulting in the loop terminating only when all channels have been closed. The *timeout* argument sets the timeout parameter for the appropriate **select()** or **poll()** call, measured in seconds; the default is 30 seconds. The *use_poll* parameter, if true, indicates that **poll()** should be used in preference to **select()** (the default is `False`).

The *map* parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If *map* is omitted, a global map is used. Channels (instances of **asyncore.dispatcher**, **asynchat.async_chat** and subclasses thereof) can freely be mixed in the map.

class asyncore.dispatcher

The **dispatcher** class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are:

Event	Description
handle_connect()	Implied by the first read or write event
handle_close()	Implied by a read event with no data available
handle_accept()	Implied by a read event on a listening socket

During asynchronous processing, each mapped channel's **readable()** and **writable()** methods are used to determine whether the channel's socket should be added to the list of channels **select()**ed or **poll()**ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

handle_read()

Called when the asynchronous loop detects that a **read()** call on the channel's socket will succeed.

handle_write()

Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]
```

handle_expt()

Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

handle_connect()

Called when the active opener's socket actually makes a connection. Might send a "welcome" banner, or initiate a protocol negotiation with the remote endpoint, for example.

handle_close()

Called when the socket is closed.

handle_error()

Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

handle_accept()

Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a **`connect()`** call for the local endpoint. Deprecated in version 3.2; use **`handle_accepted()`** instead.

Deprecated since version 3.2.

handle_accepted(*sock*, *addr*)

Called on listening channels (passive openers) when a connection has been established with a new remote endpoint that has issued a **`connect()`** call for the local endpoint. *sock* is a *new* socket object usable to

send and receive data on the connection, and *addr* is the address bound to the socket on the other end of the connection.

New in version 3.2.

readable()

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in read events.

writable()

Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which write events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

create_socket(*family*=*socket.AF_INET*, *type*=*socket.SOCK_STREAM*)

This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the **`socket`** documentation for information on creating sockets.

Changed in version 3.3: family and *type* arguments can be omitted.

connect(*address*)

As with the normal socket object, *address* is a tuple with the first element the host to connect to, and the second the port number.

send(*data*)

Send *data* to the remote end-point of the socket.

recv(*buffer_size*)

Read at most *buffer_size* bytes from the socket's remote end-point. An empty bytes object implies that the channel has been closed from the other end.

Note that `recv()` may raise `BlockingIOError`, even though `select.select()` or `select.poll()` has reported the socket ready for reading.

listen(*backlog*)

Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

bind(*address*)

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — refer to the `socket` documentation for more information.) To mark the socket as re-usable (setting the **`SO_REUSEADDR`** option), call the `dispatcher` object's **`set_reuse_addr()`** method.

accept()

Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either `None` or a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection. When `None` is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.

close()

Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

class asyncore.dispatcher_with_send

A **dispatcher** subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use **asynchat.async_chat**.

class asyncore.file_dispatcher

A file_dispatcher takes a file descriptor or file object along with an optional map argument and wraps it for use with the **poll()** or **loop()** functions. If provided a file object or anything with a **fileno()** method, that method will be called and passed to the **file_wrapper** constructor.

Availability: Unix.

class asyncore.file_wrapper

A file_wrapper takes an integer file descriptor and calls **os.dup()** to duplicate the handle so that the original handle may be closed independently of the file_wrapper. This class implements sufficient methods to emulate a socket for use by the **file_dispatcher** class.

Availability: Unix.

asyncore Example basic HTTP client

Here is a very basic HTTP client that uses the **dispatcher** class to implement its socket handling:

```
import asyncore

class HTTPClient(asyncore.dispatcher):
```

```
    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.connect( (host, 80) )
        self.buffer = bytes('GET %s HTTP/1.0\r\nHost: %s
                            (path, host), 'ascii')

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print(self.recv(8192))

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]

client = HTTPClient('www.python.org', '/')
asyncore.loop()
```

asyncore Example basic echo server

Here is a basic echo server that uses the **dispatcher** class to accept connections and dispatches the incoming connections to a handler:

```
import asyncore

class EchoHandler(asyncore.dispatcher_with_send):

    def handle_read(self):
```

```
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):

    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accepted(self, sock, addr):
        print('Incoming connection from %s' % repr(addr)
        handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()
```

audioop — Manipulate raw audio data

Deprecated since version 3.11, will be removed in version 3.13: The audioop module is deprecated (see PEP 594 [https://peps.python.org/pep-0594/#audioop] for details).

The audioop module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16, 24 or 32 bits wide, stored in bytes-like objects. All scalar items are integers, unless specified otherwise.

Changed in version 3.4: Support for 24-bit samples was added. All functions now accept any bytes-like object. String input now results in an immediate error.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

exception audioop.error

This exception is raised on all errors, such as unknown number of bytes per sample, etc.

audioop.add(*fragment1*, *fragment2*, *width*)

Return a fragment which is the addition of the two samples passed as parameters. *width* is the sample width in bytes, either `1`, `2`, `3` or `4`. Both fragments should have the same length. Samples are truncated in case of overflow.

audioop.adpcm2lin(*adpcmfragment*, *width*, *state*)

Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of **`lin2adpcm()`** for details on ADPCM coding. Return a tuple `(sample, newstate)` where the sample has the width specified in *width*.

audioop.alaw2lin(*fragment*, *width*)

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

audioop.avg(*fragment*, *width*)

Return the average over all samples in the fragment.

audioop.avgpp(*fragment*, *width*)

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

audioop.bias(*fragment*, *width*, *bias*)

Return a fragment that is the original fragment with a bias added to each sample. Samples wrap around in case of overflow.

audioop.byteswap(*fragment*, *width*)

“Byteswap” all samples in a fragment and returns the modified fragment. Converts big-endian samples to little-endian and vice versa.

New in version 3.4.

audioop.cross(*fragment*, *width*)

Return the number of zero crossings in the fragment passed as an argument.

audioop.findfactor(*fragment*, *reference*)

Return a factor *F* such that `rms(add(fragment, mul(reference, -F)))` is minimal, i.e., return the factor with which you should multiply *reference* to make it match as well as possible to *fragment*. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to `len(fragment)`.

audioop.findfit(*fragment*, *reference*)

Try to match *reference* as well as possible to a portion of *fragment* (which should be the longer fragment). This is (conceptually) done by taking slices out of *fragment*, using **`findfactor()`** to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple `(offset, factor)` where *offset* is the (integer) offset into *fragment* where the optimal match started and *factor* is the (floating-point) factor as per **`findfactor()`**.

audioop.findmax(*fragment*, *length*)

Search *fragment* for a slice of length *length* samples (not bytes!) with maximum energy, i.e., return *i* for which `rms(fragment[i*2:(i+length)*2])` is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to `len(fragment)`.

audioop.getsample(*fragment*, *width*, *index*)

Return the value of sample *index* from the fragment.

audioop.lin2adpcm(*fragment*, *width*, *state*)

Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a

standard.

state is a tuple containing the state of the coder. The coder returns a tuple `(adpcmfrag, newstate)`, and the *newstate* should be passed to the next call of **`lin2adpcm()`**. In the initial call, `None` can be passed as the state. *adpcmfrag* is the ADPCM coded fragment packed 2 4-bit values per byte.

audioop.lin2alaw(*fragment*, *width*)

Convert samples in the audio fragment to a-LAW encoding and return this as a bytes object. a-LAW is an audio encoding format whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop.lin2lin(*fragment*, *width*, *newwidth*)

Convert samples between 1-, 2-, 3- and 4-byte formats.

Note

In some audio formats, such as .WAV files, 16, 24 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```
new_frames = audioop.lin2lin(frames, old_width, 1)
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16, 24 or 32 bit width samples.

audioop.lin2ulaw(*fragment*, *width*)

Convert samples in the audio fragment to u-LAW encoding and return this as a bytes object. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop.max(*fragment*, *width*)

Return the maximum of the *absolute value* of all samples in a fragment.

audioop.maxpp(*fragment*, *width*)

Return the maximum peak-peak value in the sound fragment.

audioop.minmax(*fragment*, *width*)

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

audioop.mul(*fragment*, *width*, *factor*)

Return a fragment that has all samples in the original fragment multiplied by the floating-point value *factor*. Samples are truncated in case of overflow.

audioop.ratecv(*fragment*, *width*, *nchannels*, *inrate*, *outrate*, *state*[, *weightA*[, *weightB*]])

Convert the frame rate of the input fragment.

state is a tuple containing the state of the converter. The converter returns a tuple `(newfragment, newstate)`, and *newstate* should be passed to the next call of **`ratecv()`**. The initial call should pass `None` as the state.

The *weightA* and *weightB* arguments are parameters for a simple digital filter and default to `1` and `0` respectively.

audioop.reverse(*fragment*, *width*)

Reverse the samples in a fragment and returns the modified fragment.

audioop.rms(*fragment*, *width*)

Return the root-mean-square of the fragment, i.e. `sqrt(sum(S_i^2)/n)`.

This is a measure of the power in an audio signal.

audioop.tomono(*fragment*, *width*, *lfactor*, *rfactor*)

Convert a stereo fragment to a mono fragment. The left channel is multiplied by *lfactor* and the right channel by *rfactor* before adding the two channels to give a mono signal.

audioop.tostereo(*fragment*, *width*, *lfactor*, *rfactor*)

Generate a stereo fragment from a mono fragment. Each pair of samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by *lfactor* and right channel samples by *rfactor*.

audioop.ulaw2lin(*fragment*, *width*)

Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

Note that operations such as **`mul()`** or **`max()`** make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that:

```
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
    lsample = audioop.mul(lsample, width, lfactor)
    rsample = audioop.mul(rsample, width, rfactor)
    lsample = audioop.tostereo(lsample, width, 1, 0)
    rsample = audioop.tostereo(rsample, width, 0, 1)
    return audioop.add(lsample, rsample, width)
```

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the *initial* state (the one you passed to

lin2adpcm()) along to the decoder, not the final state (as returned by the coder). If you want to use **struct.Struct** to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted the standards in which case they will not be interoperable with the respective standards.

The **find*()** routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample:

```
def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)    # one tent
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
    ipos, factor = audioop.findfit(in_test, out_test)
    # Optional (for better cancellation):
    # factor = audioop.findfactor(in_test[ipos*2:ipos*2+
    #              out_test)
    prefill = '\0'*(pos+ipos)*2
    postfill = '\0'*(len(inputdata)-len(prefill)-len(out
    outputdata = prefill + audioop.mul(outputdata, 2, -f
    return audioop.add(inputdata, outputdata, 2)
```

`cgi` — Common Gateway Interface support

Source code: Lib/cgi.py [https://github.com/python/cpython/tree/3.11/Lib/cgi.py]

Deprecated since version 3.11, will be removed in version 3.13: The `cgi` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#cgi] for details and alternatives).

The `FieldStorage` class can typically be replaced with `urllib.parse.parse_qsl()` for `GET` and `HEAD` requests, and the `email.message` module or multipart [https://pypi.org/project/multipart/] for `POST` and `PUT`. Most utility functions have replacements.

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.

The global variable `maxlen` can be set to an integer indicating the maximum size of a POST request. POST requests larger than this size will result in a `ValueError` being raised during parsing. The default value of this variable is `0`, meaning the request size is unlimited.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server's special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client's hostname, the requested URL, the query string, and lots of other goodies) in the script's shell environment, executes the script, and sends the script's output back to the client.

The script's input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the "query string" part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```
print("Content-Type: text/html")     # HTML is following
print()                              # blank line, end of
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here's Python code that prints a simple piece of HTML:

```
print("<TITLE>CGI script output</TITLE>")
print("<H1>This is my first CGI script</H1>")
print("Hello, world!")
```

Using the cgi module

Begin by writing `import cgi`.

When you write a new script, consider adding these lines:

```
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the web browser if any errors occur. If you'd rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this:

```
import cgitb
cgitb.enable(display=0, logdir="/path/to/logdir")
```

It's very helpful to use this feature during script development. The reports produced by **`cgitb`** provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, use the **`FieldStorage`** class. If the form contains non-ASCII characters, use the *encoding* keyword parameter set to the value of the encoding defined for the document. It is usually contained in the META tag in the HEAD section of the HTML document or by the *Content-Type* header. This reads the form contents from the standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.

The **`FieldStorage`** instance can be indexed like a Python dictionary. It allows membership testing with the **`in`** operator, and also supports the standard dictionary method **`keys()`** and the built-in function **`len()`**. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional *keep_blank_values* keyword parameter when creating the **`FieldStorage`** instance.

For instance, the following code (which assumes that the *Content-Type* header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
```

```
    print("<H1>Error</H1>")
    print("Please fill in the name and addr fields.")
    return
print("<p>name:", form["name"].value)
print("<p>addr:", form["addr"].value)
...further form processing here...
```

Here the fields, accessed through `form[key]`, are themselves instances of **`FieldStorage`** (or **`MiniFieldStorage`**, depending on the form encoding). The **`value`** attribute of the instance yields the string value of the field. The **`getvalue()`** method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a **`FieldStorage`** or **`MiniFieldStorage`** instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If you expect this possibility (when your HTML form contains multiple fields with the same name), use the **`getlist()`** method, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas:

```
value = form.getlist("username")
usernames = ",".join(value)
```

If a field represents an uploaded file, accessing the value via the **`value`** attribute or the **`getvalue()`** method reads the entire file in memory as bytes. This may not be what you want. You can test for an uploaded file by testing either the **`filename`** attribute or the **`file`** attribute. You can then read the data from the **`file`** attribute before it is automatically closed as part of the garbage collection of the **`FieldStorage`** instance (the **`read()`** and **`readline()`** methods will return bytes):

```
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
```

```
linecount = 0
while True:
    line = fileitem.file.readline()
    if not line: break
    linecount = linecount + 1
```

FieldStorage objects also support being used in a **with** statement, which will automatically close them when done.

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the **done** attribute of the object for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive *multipart/** encoding). When this occurs, the item will be a dictionary-like **FieldStorage** item. This can be determined by testing its **type** attribute, which should be *multipart/form-data* (or perhaps another MIME type matching *multipart/**). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the "old" format (as the query string or as a single data part of type *application/x-www-form-urlencoded*), the items will actually be instances of the class **MiniFieldStorage**. In this case, the **list**, **file**, and **filename** attributes are always `None`.

A form submitted via POST that also has a query string will contain both **FieldStorage** and **MiniFieldStorage** items.

Changed in version 3.4: The **file** attribute is automatically closed upon the garbage collection of the creating **FieldStorage** instance.

Changed in version 3.5: Added support for the context management protocol to the **FieldStorage** class.

Higher Level Interface

The previous section explains how to read CGI form data using the **`FieldStorage`** class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there's only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:

```
user = form.getvalue("user").upper()
```

The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another `user=foo` pair to the query string, then the script would crash, because in this situation the `getvalue("user")` method call returns a list instead of a string. Calling the **`upper()`** method on a list is not valid (since lists do

not have a method of this name) and results in an **AttributeError** exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods **getfirst()** and **getlist()** provided by this higher level interface.

FieldStorage.getfirst(*name*, *default*=*None*)

> This method always returns only one value associated with form field *name*. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on. 1 If no such form field or value exists then the method returns the value specified by the optional parameter *default*. This parameter defaults to `None` if not specified.

FieldStorage.getlist(*name*)

> This method always returns a list of values associated with form field *name*. The method returns an empty list if no such form field or value exists for *name*. It returns a list consisting of one item if only one such value exists.

Using these methods you can write nice compact code:

```
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()    # This way i
for item in form.getlist("item"):
    do_something(item)
```

Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other

circumstances.

cgi.parse(*fp=None*, *environ=os.environ*, *keep_blank_values=False*, *strict_parsing=False*, *separator='&'*)

Parse a query in the environment or from a file (the file defaults to `sys.stdin`). The *keep_blank_values*, *strict_parsing* and *separator* parameters are passed to **`urllib.parse.parse_qs()`** unchanged.

Deprecated since version 3.11, will be removed in version 3.13: This function, like the rest of the **`cgi`** module, is deprecated. It can be replaced by calling **`urllib.parse.parse_qs()`** directly on the desired query string (except for `multipart/form-data` input, which can be handled as described for **`parse_multipart()`**).

cgi.parse_multipart(*fp*, *pdict*, *encoding='utf-8'*, *errors='replace'*, *separator='&'*)

Parse input of type *multipart/form-data* (for file uploads). Arguments are *fp* for the input file, *pdict* for a dictionary containing other parameters in the *Content-Type* header, and *encoding*, the request encoding.

Returns a dictionary just like **`urllib.parse.parse_qs()`**: keys are the field names, each value is a list of values for that field. For non-file fields, the value is a list of strings.

This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the **`FieldStorage`** class instead which is much more flexible.

Changed in version 3.7: Added the *encoding* and *errors* parameters. For non-file fields, the value is now a list of strings, not bytes.

Changed in version 3.10: Added the *separator* parameter.

Deprecated since version 3.11, will be removed in version 3.13: This function, like the rest of the **`cgi`** module, is deprecated. It can be replaced with the functionality in the **`email`**

package (e.g. **email.message.EmailMessage**/**email.message.Message**) which implements the same MIME RFCs, or with the multipart [https://pypi.org/project/multipart/] PyPI project.

cgi.parse_header(*string*)

Parse a MIME header (such as *Content-Type*) into a main value and a dictionary of parameters.

Deprecated since version 3.11, will be removed in version 3.13: This function, like the rest of the **cgi** module, is deprecated. It can be replaced with the functionality in the **email** package, which implements the same MIME RFCs.

For example, with **email.message.EmailMessage**:

```
from email.message import EmailMessage
msg = EmailMessage()
msg['content-type'] = 'application/json; charset="u
main, params = msg.get_content_type(), msg['content
```

cgi.test()

Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML format.

cgi.print_environ()

Format the shell environment in HTML.

cgi.print_form(*form*)

Format a form in HTML.

cgi.print_directory()

Format the current directory in HTML.

cgi.print_environ_usage()

Print a list of useful (used by CGI) environment variables in

HTML.

Caring about security

There's one important rule: if you invoke an external program (via **`os.system()`**, **`os.popen()`** or other functions with similar functionality), make very sure you don't pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn't have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.

Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory `cgi-bin` in the server tree.

Make sure that your script is readable and executable by "others"; the Unix file mode should be `0o755` octal (use `chmod 0755 filename`). Make sure that the first line of the script contains `#!` starting in column 1 followed by the pathname of the Python interpreter, for instance:

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by "others".

Make sure that any files your script needs to read or write are readable or writable, respectively, by "others" — their mode should be `0o644` for readable and `0o666` for writable. This is because,

for security reasons, the HTTP server executes your script as user "nobody", without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server's cgi-bin directory) and the set of environment variables is also different from what you get when you log in. In particular, don't count on the shell's search path for executables (**PATH**) or the Python module search path (**PYTHONPATH**) to be set to anything interesting.

If you need to load modules from a directory which is not on Python's default module search path, you can change the path in your script, before importing other modules. For example:

```
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server's documentation (it will usually have a section on CGI scripts).

Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There's one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won't execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.

Debugging CGI scripts

First of all, check for trivial installation errors — reading the section

above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (`cgi.py`) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML format. Give it the right mode etc., and send it a request. If it's installed in the standard `cgi-bin` directory, it should be possible to send it a request by entering a URL into your browser of the form:

```
http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At
```

If this gives an error of type 404, the server cannot find the script – perhaps you need to install it in a different directory. If it gives another error, there's an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as "addr" with value "At Home" and "name" with value "Joe Blow"), the `cgi.py` script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the **`cgi`** module's **`test()`** function from your script: replace its main code with the single statement

```
cgi.test()
```

This should produce the same results as those gotten from installing the `cgi.py` file itself.

When an ordinary Python script raises an unhandled exception (for whatever reason: of a typo in a module name, a file that can't be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server's log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute *some* code, you can easily send tracebacks to the web browser using the **`cgitb`** module. If you haven't done so already, just add the lines:

```
import cgitb
cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the **cgitb** module, you can use an even more robust approach (which only uses built-in modules):

```
import sys
sys.stderr = sys.stdout
print("Content-Type: text/plain")
print()
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML interpretation is going on, the traceback will be readable.

Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server's log files. (`tail -f logfile` in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names —

PATH is usually not set to a very useful value in a CGI script.

- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server's `suexec` feature.
- Don't try to give a CGI script a set-uid mode. This doesn't work on most systems, and is a security liability as well.

Footnotes

1

Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.

`cgitb` — Traceback manager for CGI scripts

Source code: Lib/cgitb.py [https://github.com/python/cpython/tree/3.11/Lib/cgitb.py]

Deprecated since version 3.11, will be removed in version 3.13: The `cgitb` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#cgitb] for details).

The `cgitb` module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add this to the top of your CGI script:

```
import cgitb
cgitb.enable()
```

The options to the `enable()` function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

cgitb.enable(*display=1*, *logdir=None*, *context=5*, *format='html'*)

This function causes the `cgitb` module to take over the interpreter's default handling for exceptions by setting the value of `sys.excepthook`.

The optional argument *display* defaults to `1` and can be set to `0` to suppress sending the traceback to the browser. If the argument *logdir* is present, the traceback reports are written to files. The value of *logdir* should be a directory where these files will be placed. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to `5`. If the optional argument *format* is `"html"`, the output is formatted as HTML. Any other value forces plain text output. The default value is `"html"`.

cgitb.text(*info*, *context*=*5*)

This function handles the exception described by *info* (a 3-tuple containing the result of **`sys.exc_info()`**), formatting its traceback as text and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to `5`.

cgitb.html(*info*, *context*=*5*)

This function handles the exception described by *info* (a 3-tuple containing the result of **`sys.exc_info()`**), formatting its traceback as HTML and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to `5`.

cgitb.handler(*info*=*None*)

This function handles an exception using the default settings (that is, show a report in the browser, but don't log to a file). This can be used when you've caught an exception and want to report it using **`cgitb`**. The optional *info* argument should be a 3-tuple containing an exception type, exception value, and traceback object, exactly like the tuple returned by **`sys.exc_info()`**. If the *info* argument is not supplied, the current exception is obtained from **`sys.exc_info()`**.

`chunk` — Read IFF chunked data

Source code: Lib/chunk.py [https://github.com/python/cpython/tree/3.11/Lib/chunk.py]

Deprecated since version 3.11, will be removed in version 3.13: The `chunk` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#chunk] for details).

This module provides an interface for reading files that use EA IFF 85 chunks. [1] This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

Offset	Length	Contents
0	4	Chunk ID
4	4	Size of chunk in big-endian byte order, not including the header
8	*n*	Data bytes, where *n* is the size given in the preceding field
8 + *n*	0 or 1	Pad byte needed if *n* is odd and chunk alignment is used

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the `Chunk` class defined here is to instantiate an instance at the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with an `EOFError` exception.

class chunk.Chunk(*file*, *align*=*True*, *bigendian*=*True*, *inclheader*=*False*)

Class which represents a chunk. The *file* argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is **read()**. If the methods **seek()** and **tell()** are present and don't raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument *align* is true, chunks are assumed to be aligned on 2-byte boundaries. If *align* is false, no alignment is assumed. The default value is true. If the optional argument *bigendian* is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument *inclheader* is true, the size given in the chunk header includes the size of the header. The default value is false.

A **Chunk** object supports the following methods:

getname()

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

getsize()

Returns the size of the chunk.

close()

Close and skip to the end of the chunk. This does not close the underlying file.

The remaining methods will raise **OSError** if called after the **close()** method has been called. Before Python 3.3, they used to raise **IOError**, now an alias of **OSError**.

isatty()

Returns `False`.

seek(*pos*, *whence*=*0*)

Set the chunk's current position. The *whence* argument is optional and defaults to `0` (absolute file positioning); other values are `1` (seek relative to the current position) and `2` (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

tell()

Return the current position into the chunk.

read(*size*=*-1*)

Read at most *size* bytes from the chunk (less if the read hits the end of the chunk before obtaining *size* bytes). If the *size* argument is negative or omitted, read all data until the end of the chunk. An empty bytes object is returned when the end of the chunk is encountered immediately.

skip()

Skip to the end of the chunk. All further calls to **`read()`** for the chunk will return `b''`. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

Footnotes

"EA IFF 85" Standard for Interchange Format Files, Jerry Morrison, Electronic Arts, January 1985.

`crypt` — Function to check Unix passwords

Source code: Lib/crypt.py [https://github.com/python/cpython/tree/3.11/Lib/crypt.py]

Deprecated since version 3.11, will be removed in version 3.13: The `crypt` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#crypt] for details and alternatives). The `hashlib` module is a potential replacement for certain use cases.

This module implements an interface to the *crypt(3)* routine, which is a one-way hash function based upon a modified DES algorithm; see the Unix man page for further details. Possible uses include storing hashed passwords so you can check passwords without storing the actual password, or attempting to crack Unix passwords with a dictionary.

Notice that the behavior of this module depends on the actual implementation of the *crypt(3)* routine in the running system. Therefore, any extensions available on the current implementation will also be available on this module.

Availability: Unix, not VxWorks.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Hashing Methods

New in version 3.3.

The **crypt** module defines the list of hashing methods (not all methods are available on all platforms):

crypt.METHOD_SHA512

A Modular Crypt Format method with 16 character salt and 86 character hash based on the SHA-512 hash function. This is the strongest method.

crypt.METHOD_SHA256

Another Modular Crypt Format method with 16 character salt and 43 character hash based on the SHA-256 hash function.

crypt.METHOD_BLOWFISH

Another Modular Crypt Format method with 22 character salt and 31 character hash based on the Blowfish cipher.

New in version 3.7.

crypt.METHOD_MD5

Another Modular Crypt Format method with 8 character salt and 22 character hash based on the MD5 hash function.

crypt.METHOD_CRYPT

The traditional method with a 2 character salt and 13 characters of hash. This is the weakest method.

Module Attributes

New in version 3.3.

crypt.methods

A list of available password hashing algorithms, as `crypt.METHOD_*` objects. This list is sorted from strongest to weakest.

Module Functions

The **crypt** module defines the following functions:

crypt.crypt(*word*, *salt*=*None*)

word will usually be a user's password as typed at a prompt or in a graphical interface. The optional *salt* is either a string as returned from **mksalt()**, one of the `crypt.METHOD_*` values (though not all may be available on all platforms), or a full encrypted password including salt, as returned by this function. If *salt* is not provided, the strongest method available in **methods** will be used.

Checking a password is usually done by passing the plain-text password as *word* and the full results of a previous **crypt()** call, which should be the same as the results of this call.

salt (either a random 2 or 16 character string, possibly prefixed with `$digit$` to indicate the method) which will be used to perturb the encryption algorithm. The characters in *salt* must be in the set `[./a-zA-Z0-9]`, with the exception of Modular Crypt Format which prefixes a `$digit$`.

Returns the hashed password as a string, which will be composed of characters from the same alphabet as the salt.

Since a few *crypt(3)* extensions allow different values, with different sizes in the *salt*, it is recommended to use the full crypted password as salt when checking for a password.

Changed in version 3.3: Accept `crypt.METHOD_*` values in addition to strings for *salt*.

crypt.mksalt(*method*=*None*, *, *rounds*=*None*)

Return a randomly generated salt of the specified method. If no *method* is given, the strongest method available in **methods** is used.

The return value is a string suitable for passing as the *salt* argument to **crypt()**.

rounds specifies the number of rounds for `METHOD_SHA256`, `METHOD_SHA512` and `METHOD_BLOWFISH`. For `METHOD_SHA256` and `METHOD_SHA512` it must be an integer between `1000` and `999_999_999`, the default is `5000`. For `METHOD_BLOWFISH` it must be a power of two between `16` (2^4) and `2_147_483_648` (2^{31}), the default is `4096` (2^{12}).

New in version 3.3.

Changed in version 3.7: Added the *rounds* parameter.

Examples

A simple example illustrating typical use (a constant-time comparison operation is needed to limit exposure to timing attacks. **`hmac.compare_digest()`** is suitable for this purpose):

```
import pwd
import crypt
import getpass
from hmac import compare_digest as compare_hash

def login():
    username = input('Python login: ')
    cryptedpasswd = pwd.getpwnam(username)[1]
    if cryptedpasswd:
        if cryptedpasswd == 'x' or cryptedpasswd == '*':
            raise ValueError('no support for shadow pass
        cleartext = getpass.getpass()
        return compare_hash(crypt.crypt(cleartext, crypt
    else:
        return True
```

To generate a hash of a password using the strongest available method and check it against the original:

```
import crypt
from hmac import compare_digest as compare_hash
```

```
hashed = crypt.crypt(plaintext)
if not compare_hash(hashed, crypt.crypt(plaintext, hashe
    raise ValueError("hashed version doesn't validate ag
```

imghdr — Determine the type of an image

Source code: Lib/imghdr.py [https://github.com/python/cpython/tree/3.11/Lib/imghdr.py]

Deprecated since version 3.11, will be removed in version 3.13: The imghdr module is deprecated (see PEP 594 [https://peps.python.org/pep-0594/#imghdr] for details and alternatives).

The imghdr module determines the type of image contained in a file or byte stream.

The imghdr module defines the following function:

imghdr.what(*file*, *h*=*None*)

Tests the image data contained in the file named by *file*, and returns a string describing the image type. If optional *h* is provided, the *file* argument is ignored and *h* is assumed to contain the byte stream to test.

Changed in version 3.6: Accepts a path-like object.

The following image types are recognized, as listed below with the return value from what():

Value	Image format
'rgb'	SGI ImgLib Files
'gif'	GIF 87a and 89a Files
'pbm'	Portable Bitmap Files
'pgm'	Portable Graymap Files
'ppm'	Portable Pixmap Files
'tiff'	TIFF Files
'rast'	Sun Raster Files
'xbm'	X Bitmap Files

jpeg	JPEG data in JFIF or Exif formats
bmp	BMP files
png	Portable Network Graphics
webp	WebP files
exr	OpenEXR Files

New in version 3.5: The *exr* and *webp* formats were added.

You can extend the list of file types **imghdr** can recognize by appending to this variable:

imghdr.tests

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When **what()** is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```
>>> import imghdr
>>> imghdr.what('bass.gif')
'gif'
```

imp — Access the import internals

Source code: Lib/imp.py [https://github.com/python/cpython/tree/3.11/Lib/imp.py]

Deprecated since version 3.4, will be removed in version 3.12: The imp module is deprecated in favor of importlib.

This module provides an interface to the mechanisms used to implement the import statement. It defines the following constants and functions:

imp.get_magic()

Return the magic string value used to recognize byte-compiled code files (.pyc files). (This value may be different for each Python version.)

Deprecated since version 3.4: Use importlib.util.MAGIC_NUMBER instead.

imp.get_suffixes()

Return a list of 3-element tuples, each describing a particular type of module. Each triple has the form (suffix, mode, type), where *suffix* is a string to be appended to the module name to form the filename to search for, *mode* is the mode string to pass to the built-in open() function to open the file (this can be 'r' for text files or 'rb' for binary files), and *type* is the file type, which has one of the values PY_SOURCE, PY_COMPILED, or C_EXTENSION, described below.

Deprecated since version 3.3: Use the constants defined on importlib.machinery instead.

imp.find_module(*name*[, *path*])

Try to find the module *name*. If *path* is omitted or `None`, the list of directory names given by `sys.path` is searched, but first a few special places are searched: the function tries to find a built-in module with the given name (**`C_BUILTIN`**), then a frozen module (**`PY_FROZEN`**), and on some systems some other places are looked in as well (on Windows, it looks in the registry which may point to a specific file).

Otherwise, *path* must be a list of directory names; each directory is searched for files with any of the suffixes returned by **`get_suffixes()`** above. Invalid names in the list are silently ignored (but all list items must be strings).

If search is successful, the return value is a 3-element tuple `(file, pathname, description)`:

file is an open file object positioned at the beginning, *pathname* is the pathname of the file found, and *description* is a 3-element tuple as contained in the list returned by **`get_suffixes()`** describing the kind of module found.

If the module is built-in or frozen then *file* and *pathname* are both `None` and the *description* tuple contains empty strings for its suffix and mode; the module type is indicated as given in parentheses above. If the search is unsuccessful, **`ImportError`** is raised. Other exceptions indicate problems with the arguments or environment.

If the module is a package, *file* is `None`, *pathname* is the package path and the last item in the *description* tuple is **`PKG_DIRECTORY`**.

This function does not handle hierarchical module names (names containing dots). In order to find *P.M*, that is, submodule *M* of package *P*, use **`find_module()`** and **`load_module()`** to find and load package *P*, and then use **`find_module()`** with the *path* argument set to `P.__path__`. When *P* itself has a dotted name, apply this recipe recursively.

Deprecated since version 3.3: Use **`importlib.util.find_spec()`** instead unless Python 3.3 compatibility is required, in which case use **`importlib.find_loader()`**. For example usage of the former case, see the Examples section of the **`importlib`** documentation.

imp.load_module(*name*, *file*, *pathname*, *description*)

Load a module that was previously found by **`find_module()`** (or by an otherwise conducted search yielding compatible results). This function does more than importing the module: if the module was already imported, it will reload the module! The *name* argument indicates the full module name (including the package name, if this is a submodule of a package). The *file* argument is an open file, and *pathname* is the corresponding file name; these can be `None` and `''`, respectively, when the module is a package or not being loaded from a file. The *description* argument is a tuple, as would be returned by **`get_suffixes()`**, describing what kind of module must be loaded.

If the load is successful, the return value is the module object; otherwise, an exception (usually **`ImportError`**) is raised.

Important: the caller is responsible for closing the *file* argument, if it was not `None`, even when an exception is raised. This is best done using a **`try`** … **`finally`** statement.

Deprecated since version 3.3: If previously used in conjunction with **`imp.find_module()`** then consider using **`importlib.import_module()`**, otherwise use the loader returned by the replacement you chose for **`imp.find_module()`**. If you called **`imp.load_module()`** and related functions directly with file path arguments then use a combination of **`importlib.util.spec_from_file_location()`** and **`importlib.util.module_from_spec()`**. See the Examples section of the **`importlib`** documentation for details of the various approaches.

imp.new_module(*name*)

Return a new empty module object called *name*. This object is *not* inserted in `sys.modules`.

Deprecated since version 3.4: Use **`importlib.util.module_from_spec()`** instead.

imp.reload(*module*)

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (the same as the *module* argument).

When `reload(module)` is executed:

- Python modules' code is recompiled and the module-level code reexecuted, defining a new set of objects which are bound to names in the module's dictionary. The `init` function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.
- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage

if it maintains a global table or cache of objects — with a **try** statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is legal though generally not very useful to reload built-in or dynamically loaded modules, except for **sys**, **__main__** and **builtins**. In many cases, however, extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using **from** … **import** …, calling **reload()** for the other module does not redefine the objects imported from it — one way around this is to re-execute the **from** statement, another is to use **import** and qualified names (*module*.*name*) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances — they continue to use the old class definition. The same is true for derived classes.

Changed in version 3.3: Relies on both `__name__` and `__loader__` being defined on the module being reloaded instead of just `__name__`.

Deprecated since version 3.4: Use **importlib.reload()** instead.

The following functions are conveniences for handling **PEP 3147** [https://peps.python.org/pep-3147/] byte-compiled file paths.

New in version 3.2.

imp.cache_from_source(*path*, *debug_override*=*None*)

Return the **PEP 3147** [https://peps.python.org/pep-3147/] path to the byte-compiled file associated with the source *path*. For

example, if *path* is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The `cpython-32` string comes from the current magic tag (see **`get_tag()`**; if **`sys.implementation.cache_tag`** is not defined then **`NotImplementedError`** will be raised). By passing in `True` or `False` for *debug_override* you can override the system's value for `__debug__`, leading to optimized bytecode.

path need not exist.

Changed in version 3.3: If **`sys.implementation.cache_tag`** is `None`, then **`NotImplementedError`** is raised.

Deprecated since version 3.4: Use **`importlib.util.cache_from_source()`** instead.

Changed in version 3.5: The *debug_override* parameter no longer creates a `.pyo` file.

imp.source_from_cache(*path*)

Given the *path* to a **PEP 3147** [https://peps.python.org/pep-3147/] file name, return the associated source code file path. For example, if *path* is `/foo/bar/__pycache__/baz.cpython-32.pyc` the returned path would be `/foo/bar/baz.py`. *path* need not exist, however if it does not conform to **PEP 3147** [https://peps.python.org/pep-3147/] format, a **`ValueError`** is raised. If **`sys.implementation.cache_tag`** is not defined, **`NotImplementedError`** is raised.

Changed in version 3.3: Raise **`NotImplementedError`** when **`sys.implementation.cache_tag`** is not defined.

Deprecated since version 3.4: Use **`importlib.util.source_from_cache()`** instead.

imp.get_tag()

Return the **PEP 3147** [https://peps.python.org/pep-3147/] magic tag

string matching this version of Python's magic number, as returned by **`get_magic()`**.

Deprecated since version 3.4: Use **`sys.implementation.cache_tag`** directly starting in Python 3.3.

The following functions help interact with the import system's internal locking mechanism. Locking semantics of imports are an implementation detail which may vary from release to release. However, Python ensures that circular imports work without any deadlocks.

imp.lock_held()

Return `True` if the global import lock is currently held, else `False`. On platforms without threads, always return `False`.

On platforms with threads, a thread executing an import first holds a global import lock, then sets up a per-module lock for the rest of the import. This blocks other threads from importing the same module until the original import completes, preventing other threads from seeing incomplete module objects constructed by the original thread. An exception is made for circular imports, which by construction have to expose an incomplete module object at some point.

Changed in version 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

Deprecated since version 3.4.

imp.acquire_lock()

Acquire the interpreter's global import lock for the current thread. This lock should be used by import hooks to ensure thread-safety when importing modules.

Once a thread has acquired the import lock, the same thread may acquire it again without blocking; the thread must

release it once for each time it has acquired it.

On platforms without threads, this function does nothing.

Changed in version 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

Deprecated since version 3.4.

imp.release_lock()

Release the interpreter's global import lock. On platforms without threads, this function does nothing.

Changed in version 3.3: The locking scheme has changed to per-module locks for the most part. A global import lock is kept for some critical tasks, such as initializing the per-module locks.

Deprecated since version 3.4.

The following constants with integer values, defined in this module, are used to indicate the search result of `find_module()`.

imp.PY_SOURCE

The module was found as a source file.

Deprecated since version 3.3.

imp.PY_COMPILED

The module was found as a compiled code object file.

Deprecated since version 3.3.

imp.C_EXTENSION

The module was found as dynamically loadable shared library.

Deprecated since version 3.3.

imp.PKG_DIRECTORY

The module was found as a package directory.

Deprecated since version 3.3.

imp.C_BUILTIN

The module was found as a built-in module.

Deprecated since version 3.3.

imp.PY_FROZEN

The module was found as a frozen module.

Deprecated since version 3.3.

class imp.NullImporter(*path_string*)

The **NullImporter** type is a **PEP 302** [https://peps.python.org/pep-0302/] import hook that handles non-directory path strings by failing to find any modules. Calling this type with an existing directory or empty string raises **ImportError**. Otherwise, a **NullImporter** instance is returned.

Instances have only one method:

find_module(*fullname*[, *path*])

This method always returns `None`, indicating that the requested module could not be found.

Changed in version 3.3: `None` is inserted into `sys.path_importer_cache` instead of an instance of **NullImporter**.

Deprecated since version 3.4: Insert `None` into `sys.path_importer_cache` instead.

Examples

The following function emulates what was the standard import

statement up to Python 1.4 (no hierarchical module names). (This *implementation* wouldn't work in that version, since **`find_module()`** has been extended and **`load_module()`** has been added in 1.4.)

```
import imp
import sys

def __import__(name, globals=None, locals=None, fromlist
    # Fast path: see if the module has already been impo
    try:
        return sys.modules[name]
    except KeyError:
        pass

    # If any of the following calls raises an exception,
    # there's a problem we can't handle -- let the calle

    fp, pathname, description = imp.find_module(name)

    try:
        return imp.load_module(name, fp, pathname, descr
    finally:
        # Since we may exit via an exception, close fp e
        if fp:
            fp.close()
```

`mailcap` — Mailcap file handling

Source code: Lib/mailcap.py [https://github.com/python/cpython/tree/3.11/Lib/mailcap.py]

Deprecated since version 3.11, will be removed in version 3.13: The `mailcap` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#mailcap] for details). The `mimetypes` module provides an alternative.

Mailcap files are used to configure how MIME-aware applications such as mail readers and web browsers react to files with different MIME types. (The name "mailcap" is derived from the phrase "mail capability".) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or web document with the MIME type *video/mpeg*, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the **xmpeg** program can be automatically started to view the file.

The mailcap format is documented in **RFC 1524** [https://datatracker.ietf.org/doc/html/rfc1524.html], "A User Agent Configuration Mechanism For Multimedia Mail Format Information", but is not an internet standard. However, mailcap files are supported on most Unix systems.

mailcap.findmatch(*caps*, *MIMEtype*, *key='view'*, *filename='/dev/null'*, *plist=[]*)

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to `os.system()`), and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, `(None, None)` is returned.

key is the name of the field desired, which represents the type of activity to be performed; the default value is 'view', since in the most common case you simply want to view the body of the MIME-typed data. Other possible values might be 'compose' and 'edit', if you wanted to create a new body of the given MIME type or alter the existing body data. See **RFC 1524** [https://datatracker.ietf.org/doc/html/rfc1524.html] for a complete list of these fields.

filename is the filename to be substituted for `%s` in the command line; the default value is `'/dev/null'` which is almost certainly not what you want, so usually you'll override it by specifying a filename.

plist can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign (`'='`), and the parameter's value. Mailcap entries can contain named parameters like `%{foo}`, which will be replaced by the value of the parameter named 'foo'. For example, if the command line `showpartial %{id} %{number} %{total}` was in a mailcap file, and *plist* was set to `['id=1', 'number=2', 'total=3']`, the resulting command line would be `'showpartial 1 2 3'`.

In a mailcap file, the "test" field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. **`findmatch()`** will automatically check such conditions and skip the entry if the check fails.

Changed in version 3.11: To prevent security issues with shell metacharacters (symbols that have special effects in a shell command line), `findmatch` will refuse to inject ASCII characters other than alphanumerics and `@+=:,./-_` into the returned command line.

If a disallowed character appears in *filename*, `findmatch` will always return `(None, None)` as if no entry was found. If such a character appears elsewhere (a value in *plist* or in

MIMEtype), `findmatch` will ignore all mailcap entries which use that value. A **`warning`** will be raised in either case.

mailcap.getcaps()

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the **`findmatch()`** function. An entry is stored as a list of dictionaries, but it shouldn't be necessary to know the details of this representation.

The information is derived from all of the mailcap files found on the system. Settings in the user's mailcap file `$HOME/.mailcap` will override settings in the system mailcap files `/etc/mailcap`, `/usr/etc/mailcap`, and `/usr/local/etc/mailcap`.

An example usage:

```
>>> import mailcap
>>> d = mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='tmp1223
('xmpeg tmp1223', {'view': 'xmpeg %s'})
```

`msilib` — Read and write Microsoft Installer files

Source code: Lib/msilib/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/msilib/__init__.py]

Deprecated since version 3.11, will be removed in version 3.13: The `msilib` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#msilib] for details).

The `msilib` supports the creation of Microsoft Installer (`.msi`) files. Because these files often contain an embedded "cabinet" file (`.cab`), it also exposes an API to create CAB files. Support for reading `.cab` files is currently not implemented; read support for the `.msi` database is possible.

This package aims to provide complete access to all tables in an `.msi` file, therefore, it is a fairly low-level API. One primary application of this package is the creation of Python installer package itself (although that currently uses a different version of `msilib`).

The package contents can be roughly split into four parts: low-level CAB routines, low-level MSI routines, higher-level MSI routines, and standard table structures.

msilib.FCICreate(*cabname*, *files*)

Create a new CAB file named *cabname*. *files* must be a list of tuples, each containing the name of the file on disk, and the name of the file inside the CAB file.

The files are added to the CAB file in the order they appear in the list. All files are added into a single CAB file, using the MSZIP compression algorithm.

Callbacks to Python for the various steps of MSI creation are currently not exposed.

msilib.UuidCreate()

Return the string representation of a new unique identifier. This wraps the Windows API functions **`UuidCreate()`** and **`UuidToString()`**.

msilib.OpenDatabase(*path*, *persist*)

Return a new database object by calling MsiOpenDatabase. *path* is the file name of the MSI file; *persist* can be one of the constants `MSIDBOPEN_CREATEDIRECT`, `MSIDBOPEN_CREATE`, `MSIDBOPEN_DIRECT`, `MSIDBOPEN_READONLY`, or `MSIDBOPEN_TRANSACT`, and may include the flag `MSIDBOPEN_PATCHFILE`. See the Microsoft documentation for the meaning of these flags; depending on the flags, an existing database is opened, or a new one created.

msilib.CreateRecord(*count*)

Return a new record object by calling **`MSICreateRecord()`**. *count* is the number of fields of the record.

msilib.init_database(*name*, *schema*, *ProductName*, *ProductCode*, *ProductVersion*, *Manufacturer*)

Create and return a new database *name*, initialize it with *schema*, and set the properties *ProductName*, *ProductCode*, *ProductVersion*, and *Manufacturer*.

schema must be a module object containing `tables` and `_Validation_records` attributes; typically, **`msilib.schema`** should be used.

The database will contain just the schema and the validation records when this function returns.

msilib.add_data(*database*, *table*, *records*)

Add all *records* to the table named *table* in *database*.

The *table* argument must be one of the predefined tables in the MSI schema, e.g. `'Feature'`, `'File'`, `'Component'`, `'Dialog'`, `'Control'`, etc.

records should be a list of tuples, each one containing all fields of a record according to the schema of the table. For optional fields, `None` can be passed.

Field values can be ints, strings, or instances of the Binary class.

class msilib.Binary(*filename*)

Represents entries in the Binary table; inserting such an object using **`add_data()`** reads the file named *filename* into the table.

msilib.add_tables(*database*, *module*)

Add all table content from *module* to *database*. *module* must contain an attribute *tables* listing all tables for which content should be added, and one attribute per table that has the actual content.

This is typically used to install the sequence tables.

msilib.add_stream(*database*, *name*, *path*)

Add the file *path* into the `_Stream` table of *database*, with the stream name *name*.

msilib.gen_uuid()

Return a new UUID, in the format that MSI typically requires (i.e. in curly braces, and with all hexdigits in uppercase).

FCICreate [https://msdn.microsoft.com/en-us/library/bb432265.aspx] UuidCreate [https://msdn.microsoft.com/en-us/library/windows/desktop/aa379205.aspx] UuidToString [https://msdn.microsoft.com/en-us/library/windows/desktop/aa379352.aspx]

Database Objects

Database.OpenView(*sql*)

Return a view object, by calling **`MSIDatabaseOpenView()`**. *sql* is the SQL statement to execute.

Database.Commit()

Commit the changes pending in the current transaction, by calling **`MSIDatabaseCommit()`**.

Database.GetSummaryInformation(*count*)

Return a new summary information object, by calling **`MsiGetSummaryInformation()`**. *count* is the maximum number of updated values.

Database.Close()

Close the database object, through **`MsiCloseHandle()`**.

New in version 3.7.

See also

MSIDatabaseOpenView [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370082.aspx] MSIDatabaseCommit [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370075.aspx] MSIGetSummaryInformation [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370301.aspx] MsiCloseHandle [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370067.aspx]

View Objects

View.Execute(*params*)

Execute the SQL query of the view, through **`MSIViewExecute()`**. If *params* is not `None`, it is a record describing actual values of the parameter tokens in the query.

View.GetColumnInfo(*kind*)

Return a record describing the columns of the view, through calling **`MsiViewGetColumnInfo()`**. *kind* can be either `MSICOLINFO_NAMES` or `MSICOLINFO_TYPES`.

View.Fetch()

Return a result record of the query, through calling **`MsiViewFetch()`**.

View.Modify(*kind*, *data*)

Modify the view, by calling **`MsiViewModify()`**. *kind* can be one of `MSIMODIFY_SEEK`, `MSIMODIFY_REFRESH`, `MSIMODIFY_INSERT`, `MSIMODIFY_UPDATE`, `MSIMODIFY_ASSIGN`, `MSIMODIFY_REPLACE`, `MSIMODIFY_MERGE`, `MSIMODIFY_DELETE`, `MSIMODIFY_INSERT_TEMPORARY`, `MSIMODIFY_VALIDATE`, `MSIMODIFY_VALIDATE_NEW`, `MSIMODIFY_VALIDATE_FIELD`, or `MSIMODIFY_VALIDATE_DELETE`.

data must be a record describing the new data.

View.Close()

Close the view, through **`MsiViewClose()`**.

windows/desktop/aa370519.aspx] MsiViewClose [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370510.aspx]

Summary Information Objects

SummaryInformation.GetProperty(*field*)

Return a property of the summary, through **`MsiSummaryInfoGetProperty()`**. *field* is the name of the property, and can be one of the constants `PID_CODEPAGE`, `PID_TITLE`, `PID_SUBJECT`, `PID_AUTHOR`, `PID_KEYWORDS`, `PID_COMMENTS`, `PID_TEMPLATE`, `PID_LASTAUTHOR`, `PID_REVNUMBER`, `PID_LASTPRINTED`, `PID_CREATE_DTM`, `PID_LASTSAVE_DTM`, `PID_PAGECOUNT`, `PID_WORDCOUNT`, `PID_CHARCOUNT`, `PID_APPNAME`, or `PID_SECURITY`.

SummaryInformation.GetPropertyCount()

Return the number of summary properties, through **`MsiSummaryInfoGetPropertyCount()`**.

SummaryInformation.SetProperty(*field*, *value*)

Set a property through **`MsiSummaryInfoSetProperty()`**. *field* can have the same values as in **`GetProperty()`**, *value* is the new value of the property. Possible value types are integer and string.

SummaryInformation.Persist()

Write the modified properties to the summary information stream, using **`MsiSummaryInfoPersist()`**.

See also

MsiSummaryInfoGetProperty [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370409.aspx] MsiSummaryInfoGetPropertyCount [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370488.aspx] MsiSummaryInfoSetProperty [https://msdn.microsoft.com/en-us/library/

windows/desktop/aa370491.aspx] MsiSummaryInfoPersist [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370490.aspx]

Record Objects

Record.GetFieldCount()

Return the number of fields of the record, through **`MsiRecordGetFieldCount()`**.

Record.GetInteger(*field*)

Return the value of *field* as an integer where possible. *field* must be an integer.

Record.GetString(*field*)

Return the value of *field* as a string where possible. *field* must be an integer.

Record.SetString(*field*, *value*)

Set *field* to *value* through **`MsiRecordSetString()`**. *field* must be an integer; *value* a string.

Record.SetStream(*field*, *value*)

Set *field* to the contents of the file named *value*, through **`MsiRecordSetStream()`**. *field* must be an integer; *value* a string.

Record.SetInteger(*field*, *value*)

Set *field* to *value* through **`MsiRecordSetInteger()`**. Both *field* and *value* must be an integer.

Record.ClearData()

Set all fields of the record to 0, through **`MsiRecordClearData()`**.

See also

MsiRecordGetFieldCount [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370366.aspx] MsiRecordSetString [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370373.aspx] MsiRecordSetStream [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370372.aspx] MsiRecordSetInteger [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370371.aspx] MsiRecordClearData [https://msdn.microsoft.com/en-us/library/windows/desktop/aa370364.aspx]

Errors

All wrappers around MSI functions raise **`MSIError`**; the string inside the exception will contain more detail.

CAB Objects

class msilib.CAB(*name*)

The class **`CAB`** represents a CAB file. During MSI construction, files will be added simultaneously to the `Files` table, and to a CAB file. Then, when all files have been added, the CAB file can be written, then added to the MSI file.

name is the name of the CAB file in the MSI file.

append(*full*, *file*, *logical*)

Add the file with the pathname *full* to the CAB file, under the name *logical*. If there is already a file named *logical*, a new file name is created.

Return the index of the file in the CAB file, and the new name of the file inside the CAB file.

commit(*database*)

Generate a CAB file, add it as a stream to the MSI file, put it into the `Media` table, and remove the generated file from the disk.

Directory Objects

class msilib.Directory(*database*, *cab*, *basedir*, *physical*, *logical*, *default*[, *componentflags*])

Create a new directory in the Directory table. There is a current component at each point in time for the directory, which is either explicitly created through **start_component()**, or implicitly when files are added for the first time. Files are added into the current component, and into the cab file. To create a directory, a base directory object needs to be specified (can be `None`), the path to the physical directory, and a logical directory name. *default* specifies the DefaultDir slot in the directory table. *componentflags* specifies the default flags that new components get.

start_component(*component* = *None*, *feature* = *None*, *flags* = *None*, *keyfile* = *None*, *uuid* = *None*)

Add an entry to the Component table, and make this component the current component for this directory. If no component name is given, the directory name is used. If no *feature* is given, the current feature is used. If no *flags* are given, the directory's default flags are used. If no *keyfile* is given, the KeyPath is left null in the Component table.

add_file(*file*, *src* = *None*, *version* = *None*, *language* = *None*)

Add a file to the current component of the directory, starting a new one if there is no current component. By default, the file name in the source and the file table will be identical. If the *src* file is specified, it is interpreted relative to the current directory. Optionally, a *version* and a *language* can be specified for the entry in the File table.

glob(*pattern*, *exclude* = *None*)

Add a list of files to the current component as specified

in the glob pattern. Individual files can be excluded in the *exclude* list.

remove_pyc()

Remove `.pyc` files on uninstall.

Directory Table [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368295.aspx] File Table [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368596.aspx] Component Table [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368007.aspx] FeatureComponents Table [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368579.aspx]

Features

class msilib.Feature(*db*, *id*, *title*, *desc*, *display*, *level*=*1*, *parent*=*None*, *directory*=*None*, *attributes*=*0*)

Add a new record to the `Feature` table, using the values *id*, *parent.id*, *title*, *desc*, *display*, *level*, *directory*, and *attributes*. The resulting feature object can be passed to the **`start_component()`** method of **`Directory`**.

set_current()

Make this feature the current feature of **`msilib`**. New components are automatically added to the default feature, unless a feature is explicitly specified.

See also

Feature Table [https://msdn.microsoft.com/en-us/library/windows/desktop/aa368585.aspx]

GUI classes

msilib provides several classes that wrap the GUI tables in an MSI database. However, no standard user interface is provided.

class msilib.Control(*dlg*, *name*)

Base class of the dialog controls. *dlg* is the dialog object the control belongs to, and *name* is the control's name.

event(*event*, *argument*, *condition* = *1*, *ordering* = *None*)

Make an entry into the `ControlEvent` table for this control.

mapping(*event*, *attribute*)

Make an entry into the `EventMapping` table for this control.

condition(*action*, *condition*)

Make an entry into the `ControlCondition` table for this control.

class msilib.RadioButtonGroup(*dlg*, *name*, *property*)

Create a radio button control named *name*. *property* is the installer property that gets set when a radio button is selected.

add(*name*, *x*, *y*, *width*, *height*, *text*, *value* = *None*)

Add a radio button named *name* to the group, at the coordinates *x*, *y*, *width*, *height*, and with the label *text*. If *value* is `None`, it defaults to *name*.

class msilib.Dialog(*db*, *name*, *x*, *y*, *w*, *h*, *attr*, *title*, *first*, *default*, *cancel*)

Return a new **Dialog** object. An entry in the `Dialog` table is made, with the specified coordinates, dialog attributes, title, name of the first, default, and cancel controls.

control(*name*, *type*, *x*, *y*, *width*, *height*, *attributes*, *property*, *text*,

control_next, *help*)

Return a new **Control** object. An entry in the `Control` table is made with the specified parameters.

This is a generic method; for specific types, specialized methods are provided.

text(*name*, *x*, *y*, *width*, *height*, *attributes*, *text*)

Add and return a `Text` control.

bitmap(*name*, *x*, *y*, *width*, *height*, *text*)

Add and return a `Bitmap` control.

line(*name*, *x*, *y*, *width*, *height*)

Add and return a `Line` control.

pushbutton(*name*, *x*, *y*, *width*, *height*, *attributes*, *text*, *next_control*)

Add and return a `PushButton` control.

radiogroup(*name*, *x*, *y*, *width*, *height*, *attributes*, *property*, *text*, *next_control*)

Add and return a `RadioButtonGroup` control.

checkbox(*name*, *x*, *y*, *width*, *height*, *attributes*, *property*, *text*, *next_control*)

Add and return a `CheckBox` control.

Precomputed tables

msilib provides a few subpackages that contain only schema and table definitions. Currently, these definitions are based on MSI version 2.0.

msilib.schema

This is the standard MSI schema for MSI 2.0, with the *tables* variable providing a list of table definitions, and *_Validation_records* providing the data for MSI validation.

msilib.sequence

This module contains table contents for the standard sequence tables: *AdminExecuteSequence*, *AdminUISequence*, *AdvtExecuteSequence*, *InstallExecuteSequence*, and *InstallUISequence*.

msilib.text

This module contains definitions for the UIText and ActionText tables, for the standard installer actions.

`nis` — Interface to Sun's NIS (Yellow Pages)

Deprecated since version 3.11, will be removed in version 3.13: The `nis` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#nis] for details).

The `nis` module gives a thin wrapper around the NIS library, useful for central administration of several hosts.

Because NIS exists only on Unix systems, this module is only available for Unix.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The `nis` module defines the following functions:

nis.match(*key*, *mapname*, *domain*=*default_domain*)

Return the match for *key* in map *mapname*, or raise an error (`nis.error`) if there is none. Both should be strings, *key* is 8-bit clean. Return value is an arbitrary array of bytes (may contain `NULL` and other joys).

Note that *mapname* is first checked if it is an alias to another name.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

nis.cat(*mapname*, *domain*=*default_domain*)

Return a dictionary mapping *key* to *value* such that `match(key, mapname)==value`. Note that both keys and values of the dictionary are arbitrary arrays of bytes.

Note that *mapname* is first checked if it is an alias to another name.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

nis.maps(*domain*=*default_domain*)

Return a list of all valid maps.

The *domain* argument allows overriding the NIS domain used for the lookup. If unspecified, lookup is in the default NIS domain.

nis.get_default_domain()

Return the system default NIS domain.

The **`nis`** module defines the following exception:

exception nis.error

An error raised when a NIS function returns an error code.

`nntplib` — NNTP protocol client

Source code: Lib/nntplib.py [https://github.com/python/cpython/tree/3.11/Lib/nntplib.py]

Deprecated since version 3.11: The `nntplib` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/] for details).

This module defines the class `NNTP` which implements the client side of the Network News Transfer Protocol. It can be used to implement a news reader or poster, or automated news processors. It is compatible with **RFC 3977** [https://datatracker.ietf.org/doc/html/rfc3977.html] as well as the older **RFC 977** [https://datatracker.ietf.org/doc/html/rfc977.html] and **RFC 2980** [https://datatracker.ietf.org/doc/html/rfc2980.html].

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```
>>> s = nntplib.NNTP('news.gmane.io')
>>> resp, count, first, last, name = s.group('gmane.comp
>>> print('Group', name, 'has', count, 'articles, range'
Group gmane.comp.python.committers has 1096 articles, ra
>>> resp, overviews = s.over((last - 9, last))
>>> for id, over in overviews:
...     print(id, nntplib.decode_header(over['subject'])
```

```
...
1087 Re: Commit privileges for Łukasz Langa
1088 Re: 3.2 alpha 2 freeze
1089 Re: 3.2 alpha 2 freeze
1090 Re: Commit privileges for Łukasz Langa
1091 Re: Commit privileges for Łukasz Langa
1092 Updated ssh key
1093 Re: Updated ssh key
1094 Re: Updated ssh key
1095 Hello fellow committers!
1096 Re: Hello fellow committers!
>>> s.quit()
'205 Bye!'
```

To post an article from a binary file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup):

```
>>> s = nntplib.NNTP('news.gmane.io')
>>> f = open('article.txt', 'rb')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 Bye!'
```

The module itself defines the following classes:

class nntplib.NNTP(*host*, *port*=*119*, *user*=*None*, *password*=*None*, *readermode*=*None*, *usenetrc*=*False*[, *timeout*])

Return a new **NNTP** object, representing a connection to the NNTP server running on host *host*, listening at port *port*. An optional *timeout* can be specified for the socket connection. If the optional *user* and *password* are provided, or if suitable credentials are present in `/.netrc` and the optional flag *usenetrc* is true, the `AUTHINFO USER` and `AUTHINFO PASS` commands are used to identify and authenticate the user to the server. If the optional flag *readermode* is true, then a `mode reader` command is sent before authentication is performed. Reader mode is sometimes necessary if you are

connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as `group`. If you get unexpected **NNTPPermanentError**s, you might need to set *readermode*. The **NNTP** class supports the **with** statement to unconditionally consume **OSError** exceptions and to close the NNTP connection when done, e.g.:

```
>>> from nntplib import NNTP
>>> with NNTP('news.gmane.io') as n:
...     n.group('gmane.comp.python.committers')
...
('211 1755 1 1755 gmane.comp.python.committers', 17
>>>
```

Raises an auditing event `nntplib.connect` with arguments `self`, `host`, `port`.

All commands will raise an auditing event `nntplib.putline` with arguments `self` and `line`, where `line` is the bytes about to be sent to the remote host.

Changed in version 3.2: usenetrc is now `False` by default.

Changed in version 3.3: Support for the **with** statement was added.

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a **ValueError** to prevent the creation of a non-blocking socket.

class nntplib.NNTP_SSL(*host*, *port*=*563*, *user*=*None*, *password*=*None*, *ssl_context*=*None*, *readermode*=*None*, *usenetrc*=*False*[, *timeout*])

Return a new **NNTP_SSL** object, representing an encrypted connection to the NNTP server running on host *host*, listening at port *port*. **NNTP_SSL** objects have the same methods as **NNTP** objects. If *port* is omitted, port 563 (NNTPS) is used. *ssl_context* is also optional, and is a **SSLContext** object.

Please read Security considerations for best practices. All other parameters behave the same as for **NNTP**.

Note that SSL-on-563 is discouraged per **RFC 4642** [https://datatracker.ietf.org/doc/html/rfc4642.html], in favor of STARTTLS as described below. However, some servers only support the former.

Raises an auditing event `nntplib.connect` with arguments `self`, `host`, `port`.

All commands will raise an auditing event `nntplib.putline` with arguments `self` and `line`, where `line` is the bytes about to be sent to the remote host.

New in version 3.2.

Changed in version 3.4: The class now supports hostname check with **ssl.SSLContext.check_hostname** and *Server Name Indication* (see **ssl.HAS_SNI**).

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a **ValueError** to prevent the creation of a non-blocking socket.

exception nntplib.NNTPError

Derived from the standard exception **Exception**, this is the base class for all exceptions raised by the **nntplib** module. Instances of this class have the following attribute:

response

The response of the server if available, as a **str** object.

exception nntplib.NNTPReplyError

Exception raised when an unexpected reply is received from the server.

exception nntplib.NNTPTemporaryError

Exception raised when a response code in the range 400–499 is received.

exception nntplib.NNTPPermanentError

Exception raised when a response code in the range 500–599 is received.

exception nntplib.NNTPProtocolError

Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5.

exception nntplib.NNTPDataError

Exception raised when there is some error in the response data.

NNTP Objects

When connected, **NNTP** and **NNTP_SSL** objects support the following methods and attributes.

Attributes

NNTP.nntp_version

An integer representing the version of the NNTP protocol supported by the server. In practice, this should be `2` for servers advertising **RFC 3977** [https://datatracker.ietf.org/doc/html/rfc3977.html] compliance and `1` for others.

New in version 3.2.

NNTP.nntp_implementation

A string describing the software name and version of the NNTP server, or **None** if not advertised by the server.

New in version 3.2.

Methods

The *response* that is returned as the first item in the return tuple of almost all methods is the server's response: a string beginning with a three-digit code. If the server's response indicates an error, the method raises one of the above exceptions.

Many of the following methods take an optional keyword-only argument *file*. When the *file* argument is supplied, it must be either a file object opened for binary writing, or the name of an on-disk file to be written to. The method will then write any data returned by the server (except for the response line and the terminating dot) to the file; any list of lines, tuples or objects that the method normally returns will be empty.

Changed in version 3.2: Many of the following methods have been reworked and fixed, which makes them incompatible with their 3.1 counterparts.

NNTP.quit()

Send a `QUIT` command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.

NNTP.getwelcome()

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

NNTP.getcapabilities()

Return the **RFC 3977** [https://datatracker.ietf.org/doc/html/rfc3977.html] capabilities advertised by the server, as a **`dict`** instance mapping capability names to (possibly empty) lists of values. On legacy servers which don't understand the `CAPABILITIES` command, an empty dictionary is returned instead.

```
>>> s = NNTP('news.gmane.io')
>>> 'POST' in s.getcapabilities()
True
```

New in version 3.2.

NNTP.login(*user=None*, *password=None*, *usenetrc=True*)

Send `AUTHINFO` commands with the user name and password. If *user* and *password* are `None` and *usenetrc* is true, credentials from `~/.netrc` will be used if possible.

Unless intentionally delayed, login is normally performed during the **`NNTP`** object initialization and separately calling this function is unnecessary. To force authentication to be delayed, you must not set *user* or *password* when creating the object, and must set *usenetrc* to False.

New in version 3.2.

NNTP.starttls(*context=None*)

Send a `STARTTLS` command. This will enable encryption on the NNTP connection. The *context* argument is optional and should be a **`ssl.SSLContext`** object. Please read Security considerations for best practices.

Note that this may not be done after authentication information has been transmitted, and authentication occurs by default if possible during a **`NNTP`** object initialization. See **`NNTP.login()`** for information on suppressing this behavior.

New in version 3.2.

Changed in version 3.4: The method now supports hostname check with **`ssl.SSLContext.check_hostname`** and *Server Name Indication* (see **`ssl.HAS_SNI`**).

NNTP.newgroups(*date*, *, *file=None*)

Send a `NEWGROUPS` command. The *date* argument should be a **`datetime.date`** or **`datetime.datetime`** object. Return a pair `(response, groups)` where *groups* is a list representing the groups that are new since the given *date*. If *file* is supplied, though, then *groups* will be empty.

```
>>> from datetime import date, timedelta
>>> resp, groups = s.newgroups(date.today() - timed
>>> len(groups)
85
>>> groups[0]
GroupInfo(group='gmane.network.tor.devel', last='4'
```

NNTP.newnews(*group*, *date*, *, *file*=*None*)

Send a `NEWNEWS` command. Here, *group* is a group name or `'*'`, and *date* has the same meaning as for **`newgroups()`**. Return a pair `(response, articles)` where *articles* is a list of message ids.

This command is frequently disabled by NNTP server administrators.

NNTP.list(*group_pattern*=*None*, *, *file*=*None*)

Send a `LIST` or `LIST ACTIVE` command. Return a pair `(response, list)` where *list* is a list of tuples representing all the groups available from this NNTP server, optionally matching the pattern string *group_pattern*. Each tuple has the form `(group, last, first, flag)`, where *group* is a group name, *last* and *first* are the last and first article numbers, and *flag* usually takes one of these values:

- `y`: Local postings and articles from peers are allowed.
- `m`: The group is moderated and all postings must be approved.
- `n`: No local postings are allowed, only articles from peers.
- `j`: Articles from peers are filed in the junk group instead.
- `x`: No local postings, and articles from peers are ignored.
- `=foo.bar`: Articles are filed in the `foo.bar` group instead.

If *flag* has another value, then the status of the newsgroup should be considered unknown.

This command can return very large results, especially if *group_pattern* is not specified. It is best to cache the results offline unless you really need to refresh them.

Changed in version 3.2: group_pattern was added.

NNTP.descriptions(*grouppattern*)

Send a `LIST NEWSGROUPS` command, where *grouppattern* is a wildmat string as specified in **RFC 3977** [https://datatracker.ietf.org/doc/html/rfc3977.html] (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair `(response, descriptions)`, where *descriptions* is a dictionary mapping group names to textual descriptions.

```
>>> resp, descs = s.descriptions('gmane.comp.python
>>> len(descs)
295
>>> descs.popitem()
('gmane.comp.python.bio.general', 'BioPython discus
```

NNTP.description(*group*)

Get a description for a single group *group*. If more than one group matches (if 'group' is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use **`descriptions()`**.

NNTP.group(*name*)

Send a `GROUP` command, where *name* is the group name. The group is selected as the current group, if it exists. Return a tuple `(response, count, first, last, name)` where *count* is the (estimated) number of articles in the group, *first* is the first article number in the group, *last* is the last article number in the group, and *name* is the group name.

NNTP.over(*message_spec*, *, *file*=*None*)

Send an `OVER` command, or an `XOVER` command on legacy

servers. *message_spec* can be either a string representing a message id, or a `(first, last)` tuple of numbers indicating a range of articles in the current group, or a `(first, None)` tuple indicating a range of articles starting from *first* to the last article in the current group, or **None** to select the current article in the current group.

Return a pair `(response, overviews)`. *overviews* is a list of `(article_number, overview)` tuples, one for each article selected by *message_spec*. Each *overview* is a dictionary with the same number of items, but this number depends on the server. These items are either message headers (the key is then the lower-cased header name) or metadata items (the key is then the metadata name prepended with `":"`). The following items are guaranteed to be present by the NNTP specification:

- the `subject`, `from`, `date`, `message-id` and `references` headers
- the `:bytes` metadata: the number of bytes in the entire raw article (including headers and body)
- the `:lines` metadata: the number of lines in the article body

The value of each item is either a string, or **None** if not present.

It is advisable to use the **decode_header()** function on header values when they may contain non-ASCII characters:

```
>>> _, _, first, last, _ = s.group('gmane.comp.pyth
>>> resp, overviews = s.over((last, last))
>>> art_num, over = overviews[0]
>>> art_num
117216
>>> list(over.keys())
['xref', 'from', ':lines', ':bytes', 'references',
>>> over['from']
'=?UTF-8?B?Ik1hcnRpbiB2LiBMw7Z3aXMi?= <martin@v.loe
>>> nntplib.decode_header(over['from'])
```

```
'"Martin v. Löwis" <martin@v.loewis.de>'
```

New in version 3.2.

NNTP.help(*, *file*=*None*)

Send a `HELP` command. Return a pair `(response, list)` where *list* is a list of help strings.

NNTP.stat(*message_spec*=*None*)

Send a `STAT` command, where *message_spec* is either a message id (enclosed in `'<'` and `'>'`) or an article number in the current group. If *message_spec* is omitted or **`None`**, the current article in the current group is considered. Return a triple `(response, number, id)` where *number* is the article number and *id* is the message id.

```
>>> _, _, first, last, _ = s.group('gmane.comp.pyth
>>> resp, number, message_id = s.stat(first)
>>> number, message_id
(9099, '<20030112190404.GE29873@epoch.metaslash.com
```

NNTP.next()

Send a `NEXT` command. Return as for **`stat()`**.

NNTP.last()

Send a `LAST` command. Return as for **`stat()`**.

NNTP.article(*message_spec*=*None*, *, *file*=*None*)

Send an `ARTICLE` command, where *message_spec* has the same meaning as for **`stat()`**. Return a tuple `(response, info)` where *info* is a **`namedtuple`** with three attributes *number*, *message_id* and *lines* (in that order). *number* is the article number in the group (or 0 if the information is not available), *message_id* the message id as a string, and *lines* a list of lines (without terminating newlines) comprising the raw message including headers and body.

```
>>> resp, info = s.article('<20030112190404.GE29873
>>> info.number
0
>>> info.message_id
'<20030112190404.GE29873@epoch.metaslash.com>'
>>> len(info.lines)
65
>>> info.lines[0]
b'Path: main.gmane.org!not-for-mail'
>>> info.lines[1]
b'From: Neal Norwitz <neal@metaslash.com>'
>>> info.lines[-3:]
[b'There is a patch for 2.3 as well as 2.2.', b'', 
```

NNTP.head(*message_spec=None*, *, *file=None*)

Same as **`article()`**, but sends a `HEAD` command. The *lines* returned (or written to *file*) will only contain the message headers, not the body.

NNTP.body(*message_spec=None*, *, *file=None*)

Same as **`article()`**, but sends a `BODY` command. The *lines* returned (or written to *file*) will only contain the message body, not the headers.

NNTP.post(*data*)

Post an article using the `POST` command. The *data* argument is either a file object opened for binary reading, or any iterable of bytes objects (representing raw lines of the article to be posted). It should represent a well-formed news article, including the required headers. The **`post()`** method automatically escapes lines beginning with `.` and appends the termination line.

If the method succeeds, the server's response is returned. If the server refuses posting, a **`NNTPReplyError`** is raised.

NNTP.ihave(*message_id*, *data*)

Send an `IHAVE` command. *message_id* is the id of the message to send to the server (enclosed in `'<'` and `'>'`). The *data* parameter and the return value are the same as for **`post()`**.

NNTP.date()

Return a pair `(response, date)`. *date* is a **`datetime`** object containing the current date and time of the server.

NNTP.slave()

Send a `SLAVE` command. Return the server's *response*.

NNTP.set_debuglevel(*level*)

Set the instance's debugging level. This controls the amount of debugging output printed. The default, `0`, produces no debugging output. A value of `1` produces a moderate amount of debugging output, generally a single line per request or response. A value of `2` or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

The following are optional NNTP extensions defined in **RFC 2980** [https://datatracker.ietf.org/doc/html/rfc2980.html]. Some of them have been superseded by newer commands in **RFC 3977** [https://datatracker.ietf.org/doc/html/rfc3977.html].

NNTP.xhdr(*hdr*, *str*, *, *file=None*)

Send an `XHDR` command. The *hdr* argument is a header keyword, e.g. `'subject'`. The *str* argument should have the form `'first-last'` where *first* and *last* are the first and last article numbers to search. Return a pair `(response, list)`, where *list* is a list of pairs `(id, text)`, where *id* is an article number (as a string) and *text* is the text of the requested header for that article. If the *file* parameter is supplied, then the output of the `XHDR` command is stored in a file. If *file* is a string, then the method will open a file with that name, write to it then close it. If *file* is a file object, then it will start calling **`write()`** on it to store the lines of the command output. If *file* is supplied, then the returned *list* is an

empty list.

NNTP.xover(*start*, *end*, *, *file=None*)

Send an `XOVER` command. *start* and *end* are article numbers delimiting the range of articles to select. The return value is the same of for **`over()`**. It is recommended to use **`over()`** instead, since it will automatically use the newer `OVER` command if available.

Utility functions

The module also defines the following utility function:

nntplib.decode_header(*header_str*)

Decode a header value, un-escaping any escaped non-ASCII characters. *header_str* must be a **`str`** object. The unescaped value is returned. Using this function is recommended to display some headers in a human readable form:

```
>>> decode_header("Some subject")
'Some subject'
>>> decode_header("=?ISO-8859-15?Q?D=E9buter_en_Pyt
'Débuter en Python'
>>> decode_header("Re: =?UTF-8?B?cHJvYmzDqG1lIGRlIG
'Re: problème de matrice'
```

`optparse` — Parser for command line options

Source code: Lib/optparse.py [https://github.com/python/cpython/tree/3.11/Lib/optparse.py]

Deprecated since version 3.2: The `optparse` module is deprecated and will not be developed further; development will continue with the `argparse` module.

`optparse` is a more convenient, flexible, and powerful library for parsing command-line options than the old `getopt` module. `optparse` uses a more declarative style of command-line parsing: you create an instance of `OptionParser`, populate it with options, and parse the command line. `optparse` allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using `optparse` in a simple script:

```
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
                  help="write report to FILE", metavar="
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose",
                  help="don't print status messages to s

(options, args) = parser.parse_args()
```

With these few lines of code, users of your script can now do the "usual thing" on the command-line, for example:

```
<yourscript> --file=outfile -q
```

As it parses the command line, **optparse** sets attributes of the `options` object returned by **parse_args()** based on user-supplied command-line values. When **parse_args()** returns from parsing this command line, `options.filename` will be `"outfile"` and `options.verbose` will be `False`. **optparse** supports both long and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example:

```
<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -foutfile
<yourscript> -qfoutfile
```

Additionally, users can run one of the following

```
<yourscript> -h
<yourscript> --help
```

and **optparse** will print out a brief summary of your script's options:

```
Usage: <yourscript> [options]

Options:
  -h, --help            show this help message and exit
  -f FILE, --file=FILE  write report to FILE
  -q, --quiet           don't print status messages to s
```

where the value of *yourscript* is determined at runtime (normally from `sys.argv[0]`).

Background

optparse was explicitly designed to encourage the creation of programs with straightforward, conventional command-line interfaces. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, read this section

to acquaint yourself with them.

Terminology

argument

> a string entered on the command-line, and passed by the shell to `execl()` or `execv()`. In Python, arguments are elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed). Unix shells also use the term "word".
>
> It is occasionally desirable to substitute an argument list other than `sys.argv[1:]`, so you should read "argument" as "an element of `sys.argv[1:]`, or of some other list provided as a substitute for `sys.argv[1:]`".

option

> an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options; the traditional Unix syntax is a hyphen ("-") followed by a single letter, e.g. `-x` or `-F`. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. `-x -F` is equivalent to `-xF`. The GNU project introduced `--` followed by a series of hyphen-separated words, e.g. `--file` or `--dry-run`. These are the only two option syntaxes provided by **`optparse`**.
>
> Some other option syntaxes that the world has seen include:
>
> - a hyphen followed by a few letters, e.g. `-pf` (this is *not* the same as multiple options merged into a single argument)
> - a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren't usually seen in the same program)
> - a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
> - a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by **optparse**, and they never will be. This is deliberate: the first three are non-standard on any environment, and the last only makes sense if you're exclusively targeting Windows or certain legacy platforms (e.g. VMS, MS-DOS).

option argument

an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With **optparse**, option arguments may either be in a separate argument from their option:

```
-f foo
--file foo
```

or included in the same argument:

```
-ffoo
--file=foo
```

Typically, a given option either takes an argument or it doesn't. Lots of people want an "optional option arguments" feature, meaning that some options will take an argument if they see it, and won't if they don't. This is somewhat controversial, because it makes parsing ambiguous: if `-a` takes an optional argument and `-b` is another option entirely, how do we interpret `-ab`? Because of this ambiguity, **optparse** does not support this feature.

positional argument

something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

required option

an option that must be supplied on the command-line; note that the phrase "required option" is self-contradictory in English. **optparse** doesn't prevent you from implementing required options, but doesn't give you much help at it either.

For example, consider this hypothetical command-line:

```
prog -v --report report.txt foo bar
```

`-v` and `--report` are both options. Assuming that `--report` takes one argument, `report.txt` is an option argument. `foo` and `bar` are positional arguments.

What are options for?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn't clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are `find`, `tar`, and `dd`—all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have "required options". Think about it. If it's required, then it's *not optional*! If there is a piece of information that your program absolutely requires in order to run successfully, that's what positional arguments are for.

As an example of good command-line interface design, consider the humble `cp` utility, for copying files. It doesn't make much sense to try to copy files without supplying a destination and at least one source. Hence, `cp` fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all:

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most `cp` implementations provide a bunch of options to tweak exactly how the files are copied: you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of `cp`, which is to copy either one file to another, or several files to another directory.

What are positional arguments for?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn't much matter *how* you get that information from the user—most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI: if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply—use sensible defaults whenever possible. Of course, you also want to make your programs reasonably flexible. That's what options are for. Again, it doesn't matter if they are entries in a config file, widgets in the "Preferences" dialog of a GUI, or command-line options—the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course; too many options can overwhelm users and make your code much harder to maintain.

Tutorial

While **optparse** is quite flexible and powerful, it's also straightforward to use in most cases. This section covers the code patterns that are common to any **optparse**-based program.

First, you need to import the OptionParser class; then, early in the main program, create an OptionParser instance:

```
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is:

```
parser.add_option(opt_str, ...,
                  attr=value, ...)
```

Each option has one or more option strings, such as `-f` or `--file`, and several option attributes that tell **optparse** what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g.:

```
parser.add_option("-f", "--file", ...)
```

You're free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to **OptionParser.add_option()** are effectively labels for the option defined by that call. For brevity, we will frequently refer to *encountering an option* on the command line; in reality, **optparse** encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct **optparse** to parse your program's command line:

```
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to **parse_args()**, but that's rarely necessary: by default it uses `sys.argv[1:]`.)

parse_args() returns two values:

- `options`, an object containing values for all of your options —e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- `args`, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option

attributes: **action**, **type**, **dest** (destination), and **help**. Of these, **action** is the most fundamental.

Understanding option actions

Actions tell **optparse** what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into **optparse**; adding new actions is an advanced topic covered in section Extending optparse. Most actions tell **optparse** to store a value in some variable—for example, take a string from the command line and store it in an attribute of `options`.

If you don't specify an option action, **optparse** defaults to `store`.

The store action

The most common option action is `store`, which tells **optparse** to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

For example:

```
parser.add_option("-f", "--file",
                  action="store", type="string", dest="f
```

Now let's make up a fake command line and ask **optparse** to parse it:

```
args = ["-f", "foo.txt"]
(options, args) = parser.parse_args(args)
```

When **optparse** sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to **parse_args()**, `options.filename` is `"foo.txt"`.

Some other option types supported by **optparse** are `int` and `float`. Here's an option that expects an integer argument:

```
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option: since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code

```
(options, args) = parser.parse_args(["-n42"])
print(options.num)
```

will print `42`.

If you don't specify a type, **optparse** assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter:

```
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, **optparse** figures out a sensible default from the option strings: if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, **optparse** looks at the first short option string: the default destination for `-f` is `f`.

optparse also includes the built-in `complex` type. Adding types is covered in section Extending optparse.

Handling boolean (flag) options

Flag options—set a variable to true or false when a particular option is seen—are quite common. **optparse** supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q`:

```
parser.add_option("-v", action="store_true", dest="verbo
parser.add_option("-q", action="store_false", dest="verb
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values—see below.)

When **optparse** encounters `-v` on the command line, it sets `options.verbose` to `True`; when it encounters `-q`, `options.verbose` is set to `False`.

Other actions

Some other actions supported by **optparse** are:

`"store_const"`
: store a constant value

`"append"`
: append this option's argument to a list

`"count"`
: increment a counter by one

`"callback"`
: call a specified function

These are covered in section Reference Guide, and section Option Callbacks.

Default values

All of the above examples involve setting some variable (the "destination") when certain command-line options are seen. What happens if those options are never seen? Since we didn't supply any defaults, they are all set to `None`. This is usually fine, but sometimes you want more control. **optparse** lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the verbose/quiet example. If we want **optparse** to set `verbose` to `True` unless `-q` is seen, then we can do this:

```
parser.add_option("-v", action="store_true", dest="verbo
```

```
parser.add_option("-q", action="store_false", dest="verb
```

Since default values apply to the *destination* rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent:

```
parser.add_option("-v", action="store_true", dest="verbo
parser.add_option("-q", action="store_false", dest="verb
```

Consider this:

```
parser.add_option("-v", action="store_true", dest="verbo
parser.add_option("-q", action="store_false", dest="verb
```

Again, the default value for `verbose` will be `True`: the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the **`set_defaults()`** method of OptionParser, which you can call at any time before calling **`parse_args()`**:

```
parser.set_defaults(verbose=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

Generating help

`optparse`'s ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a **`help`** value for each option, and optionally a short usage message for your whole program. Here's an OptionParser populated with user-friendly (documented) options:

```
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
```

```
                    action="store_true", dest="verbose", d
                    help="make lots of noise [default]")
parser.add_option("-q", "--quiet",
                    action="store_false", dest="verbose",
                    help="be vewwy quiet (I'm hunting wabb
parser.add_option("-f", "--filename",
                    metavar="FILE", help="write output to
parser.add_option("-m", "--mode",
                    default="intermediate",
                    help="interaction mode: novice, interm
                         "or expert [default: %default]")
```

If **optparse** encounters either `-h` or `--help` on the command-line, or if you just call **`parser.print_help()`**, it prints the following to standard output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabb
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, interm
                        expert [default: intermediate]
```

(If the help output is triggered by a help option, **optparse** exits after printing the help text.)

There's a lot going on here to help **optparse** generate the best possible help message:

- the script defines its own usage message:

  ```
  usage = "usage: %prog [options] arg1 arg2"
  ```

  optparse expands `%prog` in the usage string to the name of the current program, i.e. `os.path.basename(sys.argv[0])`. The expanded string

is then printed before the detailed option help.

If you don't supply a usage string, **optparse** uses a bland but sensible default: `"Usage: %prog [options]"`, which is fine if your script doesn't take any positional arguments.

- every option defines a help string, and doesn't worry about line-wrapping—**optparse** takes care of wrapping lines and making the help output look good.
- options that take a value indicate this fact in their automatically generated help message, e.g. for the "mode" option:

  ```
  -m MODE, --mode=MODE
  ```

  Here, "MODE" is called the meta-variable: it stands for the argument that the user is expected to supply to `-m/--mode`. By default, **optparse** converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that's not what you want—for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically generated option description:

  ```
  -f FILE, --filename=FILE
  ```

  This is important for more than just saving space, though: the manually written help text uses the meta-variable `FILE` to clue the user in that there's a connection between the semi-formal syntax `-f FILE` and the informal semantic description "write output to FILE". This is a simple but effective way to make your help text a lot clearer and more useful for end users.
- options that have a default value can include `%default` in the help string—**optparse** will replace it with **str()** of the option's default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An **OptionParser** can contain several option groups, each of which can contain several options.

An option group is obtained using the class **OptionGroup**:

class optparse.OptionGroup(*parser*, *title*, *description*=*None*)

where

- parser is the **OptionParser** instance the group will be inserted in to
- title is the group title
- description, optional, is a long description of the group

OptionGroup inherits from **OptionContainer** (like **OptionParser**) and so the **add_option()** method can be used to add an option to the group.

Once all the options are declared, using the **OptionParser** method **add_option_group()** the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an **OptionGroup** to a parser is easy:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your
                    "It is believed that some of them bi
group.add_option("-g", action="store_true", help="Group
parser.add_option_group(group)
```

This would result in the following help output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabb
  -f FILE, --filename=FILE
```

```
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, interm
                        expert [default: intermediate]

  Dangerous Options:
    Caution: use these options at your own risk.  It is
    of them bite.

    -g                  Group option.
```

A bit more complete example might involve using more than one group: still extending the previous example:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your
                    "It is believed that some of them bi
group.add_option("-g", action="store_true", help="Group
parser.add_option_group(group)

group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
                 help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
                 help="Print all SQL statements executed
group.add_option("-e", action="store_true", help="Print
parser.add_option_group(group)
```

that results in the following output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabb
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, interm
                        [default: intermediate]
```

```
  Dangerous Options:
    Caution: use these options at your own risk.  It is
    of them bite.

    -g                  Group option.

  Debug Options:
    -d, --debug         Print debug information
    -s, --sql           Print all SQL statements execute
    -e                  Print every action done
```

Another interesting method, in particular when working programmatically with option groups is:

OptionParser.get_option_group(*opt_str*)

> Return the **`OptionGroup`** to which the short or long option string *opt_str* (e.g. `'-o'` or `'--option'`) belongs. If there's no such **`OptionGroup`**, return `None`.

Printing a version string

Similar to the brief usage string, **`optparse`** can also print a version string for your program. You have to supply the string as the `version` argument to OptionParser:

```
parser = OptionParser(usage="%prog [-f] [-q]", version="
```

`%prog` is expanded just like it is in `usage`. Apart from that, `version` can contain anything you like. When you supply it, **`optparse`** automatically adds a `--version` option to your parser. If it encounters this option on the command line, it expands your `version` string (by replacing `%prog`), prints it to stdout, and exits.

For example, if your script is called `/usr/bin/foo`:

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the

`version` string:

OptionParser.print_version(*file*=*None*)

> Print the version message for the current program (`self.version`) to *file* (default stdout). As with **`print_usage()`**, any occurrence of `%prog` in `self.version` is replaced with the name of the current program. Does nothing if `self.version` is empty or undefined.

OptionParser.get_version()

> Same as **`print_version()`** but returns the version string instead of printing it.

How **`optparse`** handles errors

There are two broad classes of errors that **`optparse`** has to worry about: programmer errors and user errors. Programmer errors are usually erroneous calls to **`OptionParser.add_option()`**, e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way: raise an exception (either **`optparse.OptionError`** or **`TypeError`**) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. **`optparse`** can automatically detect some user errors, such as bad option arguments (passing `-n 4x` where `-n` takes an integer argument), missing arguments (`-n` at the end of the command line, where `-n` takes an argument of any type). Also, you can call **`OptionParser.error()`** to signal an application-defined error condition:

```
(options, args) = parser.parse_args()
...
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusi
```

In either case, **`optparse`** handles the error the same way: it prints

the program's usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes `4x` to an option that takes an integer:

```
$ /usr/bin/foo -n 4x
Usage: foo [options]

foo: error: option -n: invalid integer value: '4x'
```

Or, where the user fails to pass a value at all:

```
$ /usr/bin/foo -n
Usage: foo [options]

foo: error: -n option requires an argument
```

optparse-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling **`OptionParser.error()`** from your application code.

If **optparse**'s default error-handling behaviour does not suit your needs, you'll need to subclass OptionParser and override its **`exit()`** and/or **`error()`** methods.

Putting it all together

Here's what **optparse**-based scripts usually look like:

```
from optparse import OptionParser
...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                      help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
                      action="store_true", dest="verbose
    parser.add_option("-q", "--quiet",
```

```
                          action="store_false", dest="verbos
    ...
    (options, args) = parser.parse_args()
    if len(args) != 1:
        parser.error("incorrect number of arguments")
    if options.verbose:
        print("reading %s..." % options.filename)
    ...

if __name__ == "__main__":
    main()
```

Reference Guide

Creating the parser

The first step in using **optparse** is to create an OptionParser instance.

class optparse.OptionParser(...)

The OptionParser constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

`usage` (default: `"%prog [options]"`)

The usage summary to print when your program is run incorrectly or with a help option. When **optparse** prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value **optparse.SUPPRESS_USAGE**.

`option_list` (default: `[]`)

A list of Option objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by OptionParser subclasses), but before any

version or help options. Deprecated; use **`add_option()`** after creating the parser instead.

`option_class` (default: optparse.Option)
: Class to use when adding options to the parser in **`add_option()`**.

`version` (default: `None`)
: A version string to print when the user supplies a version option. If you supply a true value for `version`, **`optparse`** automatically adds a version option with the single option string `--version`. The substring `%prog` is expanded the same as for `usage`.

`conflict_handler` (default: `"error"`)
: Specifies what to do when options with conflicting option strings are added to the parser; see section Conflicts between options.

`description` (default: `None`)
: A paragraph of text giving a brief overview of your program. **`optparse`** reformats this paragraph to fit the current terminal width and prints it when the user requests help (after `usage`, but before the list of options).

`formatter` (default: a new **`IndentedHelpFormatter`**)
: An instance of optparse.HelpFormatter that will be used for printing help text. **`optparse`** provides two concrete classes for this purpose: IndentedHelpFormatter and TitledHelpFormatter.

`add_help_option` (default: `True`)
: If true, **`optparse`** will add a help option (with option strings `-h` and `--help`) to the parser.

`prog`
: The string to use when expanding `%prog` in `usage` and `version` instead of `os.path.basename(sys.argv[0])`.

`epilog` (default: `None`)
A paragraph of help text to print after the option help.

Populating the parser

There are several ways to populate the parser with options. The preferred way is by using **`OptionParser.add_option()`**, as shown in section Tutorial. **`add_option()`** can be called in one of two ways:

- pass it an Option instance (as returned by **`make_option()`**)
- pass it any combination of positional and keyword arguments that are acceptable to **`make_option()`** (i.e., to the Option constructor), and it will create the Option instance for you

The other alternative is to pass a list of pre-constructed Option instances to the OptionParser constructor, as in:

```
option_list = [
    make_option("-f", "--filename",
                action="store", type="string", dest="fil
    make_option("-q", "--quiet",
                action="store_false", dest="verbose"),
    ]
parser = OptionParser(option_list=option_list)
```

(**`make_option()`** is a factory function for creating Option instances; currently it is an alias for the Option constructor. A future version of **`optparse`** may split Option into several classes, and **`make_option()`** will pick the right class to instantiate. Do not instantiate Option directly.)

Defining options

Each Option instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an **`Option`** instance is with the

`add_option()` method of **`OptionParser`**.

OptionParser.add_option(*option*)
OptionParser.add_option(**opt_str*, *attr*=*value*, ...)

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new Option object. The most important option attribute is **`action`**, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, **`optparse`** raises an **`OptionError`** exception explaining your mistake.

An option's *action* determines what **`optparse`** does when it encounters this option on the command-line. The standard option actions hard-coded into **`optparse`** are:

`"store"`
: store this option's argument (default)

`"store_const"`
: store a constant value

`"store_true"`
: store `True`

`"store_false"`
: store `False`

`"append"`
: append this option's argument to a list

`"append_const"`
: append a constant value to a list

`"count"`
: increment a counter by one

`"callback"`
: call a specified function

`"help"`
: print a usage message including all options and the documentation for them

(If you don't supply an action, the default is `"store"`. For this action, you may also supply **`type`** and **`dest`** option attributes; see Standard option actions.)

As you can see, most actions involve storing or updating a value somewhere. **`optparse`** always creates a special object for this, conventionally called `options` (it happens to be an instance of **`optparse.Values`**). Option arguments (and various other values) are stored as attributes of this object, according to the **`dest`** (destination) option attribute.

For example, when you call

```
parser.parse_args()
```

one of the first things **`optparse`** does is create the `options` object:

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="
```

and the command-line being parsed includes any of the following:

```
-ffoo
-f foo
--file=foo
--file foo
```

then **optparse**, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The **type** and **dest** option attributes are almost as important as **action**, but **action** is the only one that makes sense for *all* options.

Option attributes

The following option attributes may be passed as keyword arguments to **OptionParser.add_option()**. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, **optparse** raises **OptionError**.

Option.action

(default: `"store"`)

Determines **optparse**'s behaviour when this option is seen on the command line; the available options are documented here.

Option.type

(default: `"string"`)

The argument type expected by this option (e.g., `"string"` or `"int"`); the available option types are documented here.

Option.dest

(default: derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells **optparse** where to write it: **dest** names an attribute of the `options` object that **optparse** builds as it parses the command line.

Option.default

The value to use for this option's destination if the option is not seen on the command line. See also

OptionParser.set_defaults().

Option.nargs

(default: 1)

How many arguments of type **type** should be consumed when this option is seen. If > 1, **optparse** will store a tuple of values to **dest**.

Option.const

For actions that store a constant value, the constant value to store.

Option.choices

For options of type `"choice"`, the list of strings the user may choose from.

Option.callback

For options with action `"callback"`, the callable to call when this option is seen. See section Option Callbacks for detail on the arguments passed to the callable.

Option.callback_args
Option.callback_kwargs

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.

Option.help

Help text to print for this option when listing all available options after the user supplies a **help** option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value **optparse.SUPPRESS_HELP**.

Option.metavar

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help

text. See section Tutorial for an example.

Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide **optparse**'s behaviour; a few have required attributes, which you must specify for any option using that action.

- `"store"` [relevant: **type**, **dest**, **nargs**, **choices**]

  The option must be followed by an argument, which is converted to a value according to **type** and stored in **dest**. If **nargs** > 1, multiple arguments will be consumed from the command line; all will be converted according to **type** and stored to **dest** as a tuple. See the Standard option types section.

  If **choices** is supplied (a list or tuple of strings), the type defaults to `"choice"`.

  If **type** is not supplied, it defaults to `"string"`.

  If **dest** is not supplied, **optparse** derives a destination from the first long option string (e.g., `--foo-bar` implies `foo_bar`). If there are no long option strings, **optparse** derives a destination from the first short option string (e.g., `-f` implies `f`).

  Example:

  ```
  parser.add_option("-f")
  parser.add_option("-p", type="float", nargs=3, dest
  ```

  As it parses the command line

  ```
  -f foo.txt -p 1 -3.5 4 -fbar.txt
  ```

  optparse will set

```
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- `"store_const"` [required: **`const`**; relevant: **`dest`**]

  The value **`const`** is stored in **`dest`**.

  Example:

  ```
  parser.add_option("-q", "--quiet",
                    action="store_const", const=0, de
  parser.add_option("-v", "--verbose",
                    action="store_const", const=1, de
  parser.add_option("--noisy",
                    action="store_const", const=2, de
  ```

  If `--noisy` is seen, **`optparse`** will set

  ```
  options.verbose = 2
  ```

- `"store_true"` [relevant: **`dest`**]

  A special case of `"store_const"` that stores `True` to **`dest`**.

- `"store_false"` [relevant: **`dest`**]

  Like `"store_true"`, but stores `False`.

  Example:

  ```
  parser.add_option("--clobber", action="store_true",
  parser.add_option("--no-clobber", action="store_fal
  ```

- `"append"` [relevant: **`type`**, **`dest`**, **`nargs`**, **`choices`**]

  The option must be followed by an argument, which is appended to the list in **`dest`**. If no default value for **`dest`** is supplied, an empty list is automatically created when **`optparse`** first encounters this option on the command-line. If **`nargs`** > 1, multiple arguments are consumed, and a tuple

of length **nargs** is appended to **dest**.

The defaults for **type** and **dest** are the same as for the `"store"` action.

Example:

```
parser.add_option("-t", "--tracks", action="append"
```

If `-t3` is seen on the command-line, **optparse** does the equivalent of:

```
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, `--tracks=4` is seen, it does:

```
options.tracks.append(int("4"))
```

The `append` action calls the `append` method on the current value of the option. This means that any default value specified must have an `append` method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values:

```
>>> parser.add_option("--files", action="append", d
>>> opts, args = parser.parse_args(['--files', 'ove
>>> opts.files
['~/.mypkg/defaults', 'overrides.mypkg']
```

- `"append_const"` [required: **const**; relevant: **dest**]

  Like `"store_const"`, but the value **const** is appended to **dest**; as with `"append"`, **dest** defaults to `None`, and an empty list is automatically created the first time the option is encountered.

- `"count"` [relevant: **dest**]

  Increment the integer stored at **dest**. If no default value is supplied, **dest** is set to zero before being incremented the

first time.

Example:

```
parser.add_option("-v", action="count", dest="verbo
```

The first time `-v` is seen on the command line, **optparse** does the equivalent of:

```
options.verbosity = 0
options.verbosity += 1
```

Every subsequent occurrence of `-v` results in

```
options.verbosity += 1
```

- `"callback"` [required: **callback**; relevant: **type**, **nargs**, **callback_args**, **callback_kwargs**]

  Call the function specified by **callback**, which is called as

  ```
  func(option, opt_str, value, parser, *args, **kwarg
  ```

  See section Option Callbacks for more detail.

- `"help"`

  Prints a complete help message for all the options in the current option parser. The help message is constructed from the `usage` string passed to OptionParser's constructor and the **help** string passed to every option.

  If no **help** string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value **optparse.SUPPRESS_HELP**.

  optparse automatically adds a **help** option to all OptionParsers, so you do not normally need to create one.

  Example:

  ```
  from optparse import OptionParser, SUPPRESS_HELP
  ```

```
# usually, a help option is added automatically, bu
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data fro
parser.add_option("--secret", help=SUPPRESS_HELP)
```

If **optparse** sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is `"foo.py"`):

```
Usage: foo.py [options]

Options:
  -h, --help        Show this help message and exit
  -v                Be moderately verbose
  --file=FILENAME   Input file to read data from
```

After printing the help message, **optparse** terminates your process with `sys.exit(0)`.

- `"version"`

  Prints the version number supplied to the OptionParser to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of OptionParser. Generally only relevant if the `version` argument is supplied to the OptionParser constructor. As with **help** options, you will rarely create `version` options, since **optparse** automatically adds them when needed.

Standard option types

optparse has five built-in option types: `"string"`, `"int"`, `"choice"`, `"float"` and `"complex"`. If you need to add new

option types, see section Extending optparse.

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type `"int"`) are parsed as follows:

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling **`int()`** with the appropriate base (2, 8, 10, or 16). If this fails, so will **`optparse`**, although with a more useful error message.

`"float"` and `"complex"` option arguments are converted directly with **`float()`** and **`complex()`**, with similar error-handling.

`"choice"` options are a subtype of `"string"` options. The **`choices`** option attribute (a sequence of strings) defines the set of allowed option arguments. **`optparse.check_choice()`** compares user-supplied option arguments against this master list and raises **`OptionValueError`** if an invalid string is given.

Parsing arguments

The whole point of creating and populating an OptionParser is to call its **`parse_args()`** method:

```
(options, args) = parser.parse_args(args=None, values=Nc
```

where the input parameters are

`args`
: the list of arguments to process (default: `sys.argv[1:]`)

`values`
: an **`optparse.Values`** object to store option arguments in

(default: a new instance of **Values**) – if you give an existing object, the option defaults will not be initialized on it

and the return values are

`options`
: the same object that was passed in as `values`, or the optparse.Values instance created by **optparse**

`args`
: the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply `values`, it will be modified with repeated **setattr()** calls (roughly one for every option argument stored to an option destination) and returned by **parse_args()**.

If **parse_args()** encounters any errors in the argument list, it calls the OptionParser's **error()** method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. OptionParser provides several methods to help you out:

OptionParser.disable_interspersed_args()
: Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, **optparse** normally accepts this syntax:

  ```
  prog -a arg1 -b arg2
  ```

  and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call **`disable_interspersed_args()`**. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

OptionParser.enable_interspersed_args()

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

OptionParser.get_option(*opt_str*)

Returns the Option instance with the option string *opt_str*, or `None` if no options have that option string.

OptionParser.has_option(*opt_str*)

Return `True` if the OptionParser has an option with option string *opt_str* (e.g., `-q` or `--verbose`).

OptionParser.remove_option(*opt_str*)

If the **`OptionParser`** has an option corresponding to *opt_str*, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If *opt_str* does not occur in any option belonging to this **`OptionParser`**, raises **`ValueError`**.

Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings:

```
parser.add_option("-n", "--dry-run", ...)
```

```
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own OptionParser subclass with some standard options.)

Every time you add an option, **optparse** checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

`"error"` (default)
: assume option conflicts are a programming error and raise **OptionConflictError**

`"resolve"`
: resolve option conflicts intelligently (see below)

As an example, let's define an **OptionParser** that resolves conflicts intelligently and add conflicting options to it:

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no ha
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, **optparse** detects that a previously added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```
Options:
  --dry-run     do no harm
  ...
  -n, --noisy   be noisy
```

It's possible to whittle away the option strings for a previously added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, **optparse** removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing OptionParser:

```
parser.add_option("--dry-run", ..., help="new dry-run op
```

At this point, the original `-n/--dry-run` option is no longer accessible, so **optparse** removes it, leaving this help text:

```
Options:
  ...
  -n, --noisy   be noisy
  --dry-run     new dry-run option
```

Cleanup

OptionParser instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling **`destroy()`** on your OptionParser once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your OptionParser.

Other methods

OptionParser supports several other public methods:

OptionParser.set_usage(*usage*)

> Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use **`optparse.SUPPRESS_USAGE`** to suppress a usage message.

OptionParser.print_usage(*file*=*None*)

Print the usage message for the current program (`self.usage`) to *file* (default stdout). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

OptionParser.get_usage()

Same as **`print_usage()`** but returns the usage string instead of printing it.

OptionParser.set_defaults(*dest*=*value*, ...)

Set default values for several option destinations at once. Using **`set_defaults()`** is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several "mode" options all set the same destination, any one of them can set the default, and the last one wins:

```
parser.add_option("--advanced", action="store_const
                  dest="mode", const="advanced",
                  default="novice")    # overridden
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
                  default="advanced")  # overrides
```

To avoid this confusion, use **`set_defaults()`**:

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

Option Callbacks

When **`optparse`**'s built-in actions and types aren't quite enough for your needs, you have two choices: extend **`optparse`** or define

a callback option. Extending **optparse** is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the `"callback"` action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

Defining a callback option

As always, the easiest way to define a callback option is by using the **`OptionParser.add_option()`** method. Apart from **`action`**, the only option attribute you must specify is `callback`, the function to call:

```
parser.add_option("-c", action="callback", callback=my_c
```

`callback` is a function (or other callable object), so you must have already defined `my_callback()` when you create this callback option. In this simple case, **optparse** doesn't even know if `-c` takes any arguments, which usually means that the option takes no arguments—the mere presence of `-c` on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it's covered later in this section.

optparse always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via **`callback_args`** and **`callback_kwargs`**. Thus, the minimal callback function signature is:

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

type
: has its usual meaning: as with the `"store"` or `"append"` actions, it instructs **optparse** to consume one argument and convert it to **type**. Rather than storing the converted value(s) anywhere, though, **optparse** passes it to your callback function.

nargs
: also has its usual meaning: if it is supplied and > 1, **optparse** will consume **nargs** arguments, each of which must be convertible to **type**. It then passes a tuple of converted values to your callback.

callback_args
: a tuple of extra positional arguments to pass to the callback

callback_kwargs
: a dictionary of extra keyword arguments to pass to the callback

How callbacks are called

All callbacks are called as follows:

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

`option`
: is the Option instance that's calling the callback

`opt_str`
: is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, `opt_str` will be the full, canonical option string—e.g. if the user puts `--foo` on the command-line as an abbreviation for `--foobar`, then `opt_str` will be `"--foobar"`.)

`value`

is the argument to this option seen on the command-line. **optparse** will only expect an argument if **type** is set; the type of `value` will be the type implied by the option's type. If **type** for this option is `None` (no argument expected), then `value` will be `None`. If **nargs** > 1, `value` will be a tuple of values of the appropriate type.

`parser`

is the OptionParser instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

`parser.largs`

the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify `parser.largs`, e.g. by adding more arguments to it. (This list will become `args`, the second return value of **parse_args()**.)

`parser.rargs`

the current list of remaining arguments, ie. with `opt_str` and `value` (if applicable) removed, and only the arguments following them still there. Feel free to modify `parser.rargs`, e.g. by consuming more arguments.

`parser.values`

the object where option values are by default stored (an instance of optparse.OptionValues). This lets callbacks use the same mechanism as the rest of **optparse** for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

`args`

is a tuple of arbitrary positional arguments supplied via the **callback_args** option attribute.

`kwargs`
: is a dictionary of arbitrary keyword arguments supplied via **`callback_kwargs`**.

Raising errors in a callback

The callback function should raise **`OptionValueError`** if there are any problems with the option or its argument(s). **`optparse`** catches this and terminates the program, printing the error message you supply to stderr. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

Callback example 1: trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True

parser.add_option("--foo", action="callback", callback=r
```

Of course, you could do that with the `"store_true"` action.

Callback example 2: check option order

Here's a slightly more interesting example: record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
...
parser.add_option("-a", action="callback", callback=chec
parser.add_option("-b", action="store_true", dest="b")
```

Callback example 3: check option order (generalized)

If you want to re-use this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" %
    setattr(parser.values, option.dest, 1)
...
parser.add_option("-a", action="callback", callback=chec
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=chec
```

Callback example 4: check arbitrary condition

Of course, you could put any condition in there—you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when m
                               % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("--foo",
                  action="callback", callback=check_moon
```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a `"store"` or `"append"` option: if you define **`type`**, then the option takes one argument that must be convertible to that type; if you further

define **nargs**, then the option takes **nargs** arguments.

Here's an example that just emulates the standard `"store"` action:

```
def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
...
parser.add_option("--foo",
                  action="callback", callback=store_valu
                  type="int", nargs=3, dest="foo")
```

Note that **optparse** takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don't need a callback for this example.)

Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as **optparse** doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that **optparse** normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments:

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option): halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option): halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why **optparse** doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
        if arg[:1] == "-" and len(arg) > 1 and not float
            break
        value.append(arg)

    del parser.rargs[:len(value)]
    setattr(parser.values, option.dest, value)

...
parser.add_option("-c", "--callback", dest="vararg_attr"
                  action="callback", callback=vararg_cal
```

Extending `optparse`

Since the two major controlling factors in how `optparse` interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

Adding new types

To add new types, you need to define your own subclass of `optparse`'s `Option` class. This class has a couple of attributes that

define **optparse**'s types: **TYPES** and **TYPE_CHECKER**.

Option.TYPES

> A tuple of type names; in your subclass, simply define a new tuple **TYPES** that builds on the standard one.

Option.TYPE_CHECKER

> A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:
>
> ```
> def check_mytype(option, opt, value)
> ```
>
> where `option` is an **Option** instance, `opt` is an option string (e.g., `-f`), and `value` is the string from the command line that must be checked and converted to your desired type. `check_mytype()` should return an object of the hypothetical type `mytype`. The value returned by a type-checking function will wind up in the OptionValues instance returned by **OptionParser.parse_args()**, or be passed to a callback as the `value` parameter.
>
> Your type-checking function should raise **OptionValueError** if it encounters any problems. **OptionValueError** takes a single string argument, which is passed as-is to **OptionParser**'s **error()** method, which in turn prepends the program name and the string `"error:"` and prints everything to stderr before terminating the process.

Here's a silly example that demonstrates adding a `"complex"` option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because **optparse** 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the **TYPE_CHECKER** class attribute of your Option subclass):

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (op
```

Finally, the Option subclass:

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a **copy()** of **Option.TYPE_CHECKER**, we would end up modifying the **TYPE_CHECKER** attribute of **optparse**'s Option class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other **optparse**-based script, except you have to instruct your OptionParser to use MyOption instead of Option:

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to OptionParser; if you don't use **add_option()** in the above way, you don't need to tell OptionParser which option class to use:

```
option_list = [MyOption("-c", action="store", type="comp
parser = OptionParser(option_list=option_list)
```

Adding new actions

Adding new actions is a bit trickier, because you have to understand that **optparse** has a couple of classifications for actions:

“store” actions
: actions that result in **optparse** storing a value to an attribute of the current OptionValues instance; these options require a **dest** attribute to be supplied to the Option constructor.

“typed” actions
: actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a **type** attribute to the Option constructor.

These are overlapping sets: some default “store” actions are `"store"`, `"store_const"`, `"append"`, and `"count"`, while the default “typed” actions are `"store"`, `"append"`, and `"callback"`.

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of Option (all are lists of strings):

Option.ACTIONS
: All actions must be listed in ACTIONS.

Option.STORE_ACTIONS
: “store” actions are additionally listed here.

Option.TYPED_ACTIONS
: “typed” actions are additionally listed here.

Option.ALWAYS_TYPED_ACTIONS
: Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that **optparse** assigns the default type, `"string"`, to options with no explicit type whose action is listed in **ALWAYS_TYPED_ACTIONS**.

In order to actually implement your new action, you must override Option’s **take_action()** method and add a case that recognizes

your action.

For example, let's add an `"extend"` action. This is similar to the standard `"append"` action, but instead of taking a single value from the command-line and appending it to an existing list, `"extend"` will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if `--names` is an `"extend"` option of type `"string"`, the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of Option:

```
class MyOption(Option):

    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS +

    def take_action(self, action, dest, opt, value, valu
        if action == "extend":
            lvalue = value.split(",")
            values.ensure_value(dest, []).extend(lvalue)
        else:
            Option.take_action(
                self, action, dest, opt, value, values,
```

Features of note:

- `"extend"` both expects a value on the command-line and stores that value somewhere, so it goes in both **`STORE_ACTIONS`** and **`TYPED_ACTIONS`**.
- to ensure that **`optparse`** assigns the default type of `"string"` to `"extend"` actions, we put the `"extend"` action in **`ALWAYS_TYPED_ACTIONS`** as well.

- **`MyOption.take_action()`** implements just this one new action, and passes control back to **`Option.take_action()`** for the standard **`optparse`** actions.

- `values` is an instance of the optparse_parser.Values class, which provides the very useful **`ensure_value()`** method. **`ensure_value()`** is essentially **`getattr()`** with a safety valve; it is called as

  ```
  values.ensure_value(attr, value)
  ```

  If the `attr` attribute of `values` doesn't exist or is `None`, then ensure_value() first sets it to `value`, and then returns 'value. This is very handy for actions like `"extend"`, `"append"`, and `"count"`, all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using **`ensure_value()`** means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and **`ensure_value()`** will take care of getting it right when it's needed.

ossaudiodev — Access to OSS-compatible audio devices

Deprecated since version 3.11, will be removed in version 3.13: The ossaudiodev module is deprecated (see PEP 594 [https://peps.python.org/pep-0594/#ossaudiodev] for details).

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

Changed in version 3.3: Operations in this module now raise OSError where IOError was raised.

See also

Open Sound System Programmer's Guide [http://www.opensound.com/pguide/oss.pdf]
the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see <sys/soundcard.h> on either Linux or FreeBSD for a listing.

ossaudiodev defines the following variables and functions:

exception ossaudiodev.OSSAudioError

This exception is raised on certain errors. The argument is a string describing what went wrong.

(If ossaudiodev receives an error from a system call such as **open()**, **write()**, or **ioctl()**, it raises OSError. Errors detected directly by ossaudiodev result in

OSSAudioError.)

(For backwards compatibility, the exception class is also available as `ossaudiodev.error`.)

ossaudiodev.open(*mode*)
ossaudiodev.open(*device*, *mode*)

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as **`read()`**, **`write()`**, and **`fileno()`** (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

device is the audio device filename to use. If it is not specified, this module first looks in the environment variable **`AUDIODEV`** for a device to use. If not found, it falls back to `/dev/dsp`.

mode is one of `'r'` for read-only (record) access, `'w'` for write-only (playback) access and `'rw'` for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the *first* argument is optional, and the second is required. This is a historical artifact for compatibility with the older **`linuxaudiodev`** module which **`ossaudiodev`** supersedes.

ossaudiodev.openmixer([*device*])

Open a mixer device and return an OSS mixer device object. *device* is the mixer device filename to use. If it is not specified, this module first looks in the environment variable **`MIXERDEV`** for a device to use. If not found, it falls back to `/dev/mixer`.

Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order:

1. **`setfmt()`** to set the output format
2. **`channels()`** to set the number of channels
3. **`speed()`** to set the sample rate

Alternately, you can use the **`setparameters()`** method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by **`open()`** define the following methods and (read-only) attributes:

oss_audio_device.close()

Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

oss_audio_device.fileno()

Return the file descriptor associated with the device.

oss_audio_device.read(*size*)

Read *size* bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block **`read()`** until the entire requested amount of data is available.

oss_audio_device.write(*data*)

Write a bytes-like object *data* to the audio device and return the number of bytes written. If the audio device is in blocking mode (the default), the entire data is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written—see **`writeall()`**.

Changed in version 3.5: Writable bytes-like object is now accepted.

oss_audio_device.writeall(*data*)

Write a bytes-like object *data* to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until *data* has been completely written. If the device is in blocking mode (the default), this has the same effect as **`write()`**; **`writeall()`** is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

Changed in version 3.5: Writable bytes-like object is now accepted.

Changed in version 3.2: Audio device objects also support the context management protocol, i.e. they can be used in a **`with`** statement.

The following methods each map to exactly one **`ioctl()`** system call. The correspondence is obvious: for example, **`setfmt()`** corresponds to the `SNDCTL_DSP_SETFMT` ioctl, and **`sync()`** to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying **`ioctl()`** fails, they all raise **`OSError`**.

oss_audio_device.nonblock()

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

oss_audio_device.getfmts()

Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:

Format	Description
`AFMT_MU_LAW`	a logarithmic encoding (used by Sun `.au` files and `/dev/audio`)
`AFMT_A_LAW`	a logarithmic encoding
`AFMT_IMA_ADPCM`	a 4:1 compressed format defined by the Interactive

Multimedia Association

AFMT_U8	Unsigned, 8-bit audio
AFMT_S16_LE	Signed, 16-bit audio, little-endian byte order (as used by Intel processors)
AFMT_S16_BE	Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)
AFMT_S8	Signed, 8 bit audio
AFMT_U16_LE	Unsigned, 16-bit little-endian audio
AFMT_U16_BE	Unsigned, 16-bit big-endian audio

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support **AFMT_U8**; the most common format used today is **AFMT_S16_LE**.

oss_audio_device.setfmt(*format*)

Try to set the current audio format to *format*—see **getfmts()** for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an "audio format" of **AFMT_QUERY**.

oss_audio_device.channels(*nchannels*)

Set the number of output channels to *nchannels*. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

oss_audio_device.speed(*samplerate*)

Try to set the audio sampling rate to *samplerate* samples per second. Returns the rate actually set. Most sound devices don't support arbitrary sampling rates. Common rates are:

Rate	Description
8000	default rate for `/dev/audio`
11025	speech recording
22050	
44100	CD quality audio (at 16 bits/sample and 2 channels)

oss_audio_device.sync()

Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using `sync()`.

oss_audio_device.reset()

Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling `reset()`.

oss_audio_device.post()

Tell the driver that there is likely to be a pause in the output, making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctls, or one ioctl and some simple calculations.

oss_audio_device.setparameters(*format*, *nchannels*, *samplerate*[, *strict*=*False*])

Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. *format*, *nchannels*, and *samplerate* should be as specified in the `setfmt()`, `channels()`, and `speed()` methods. If *strict* is true, `setparameters()` checks to see if each parameter was actually set to the requested value, and raises `OSSAudioError` if not. Returns a tuple (*format*, *nchannels*, *samplerate*) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of `setfmt()`, `channels()`, and `speed()`).

For example,

```
(fmt, channels, rate) = dsp.setparameters(fmt, chan
```

is equivalent to

```
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
rate = dsp.rate(rate)
```

oss_audio_device.bufsize()

Returns the size of the hardware buffer, in samples.

oss_audio_device.obufcount()

Returns the number of samples that are in the hardware buffer yet to be played.

oss_audio_device.obuffree()

Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

oss_audio_device.closed

Boolean indicating whether the device has been closed.

oss_audio_device.name

String containing the name of the device file.

oss_audio_device.mode

The I/O mode for the file, either `"r"`, `"rw"`, or `"w"`.

Mixer Device Objects

The mixer object provides two file-like methods:

oss_mixer_device.close()

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an

OSError.

oss_mixer_device.fileno()

Returns the file handle number of the open mixer device file.

Changed in version 3.2: Mixer objects also support the context management protocol.

The remaining methods are specific to audio mixing:

oss_mixer_device.controls()

This method returns a bitmask specifying the available mixer controls ("Control" being a specific mixable "channel", such as **SOUND_MIXER_PCM** or **SOUND_MIXER_SYNTH**). This bitmask indicates a subset of all available mixer controls—the **SOUND_MIXER_*** constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIXER
    # PCM is supported
    ... code ...
```

For most purposes, the **SOUND_MIXER_VOLUME** (master volume) and **SOUND_MIXER_PCM** controls should suffice—but code that uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, **SOUND_MIXER_VOLUME** does not exist.

oss_mixer_device.stereocontrols()

Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with **controls()** to determine which).

See the code example for the **controls()** function for an example of getting data from a bitmask.

oss_mixer_device.reccontrols()

Returns a bitmask specifying the mixer controls that may be used to record. See the code example for **`controls()`** for an example of reading from a bitmask.

oss_mixer_device.get(*control*)

Returns the volume of a given mixer control. The returned volume is a 2-tuple `(left_volume,right_volume)`. Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises **`OSSAudioError`** if an invalid control is specified, or **`OSError`** if an unsupported control is specified.

oss_mixer_device.set(*control*, *(left*, *right)*)

Sets the volume for a given mixer control to `(left,right)`. `left` and `right` must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple. Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard's mixers.

Raises **`OSSAudioError`** if an invalid mixer control was specified, or if the specified volumes were out-of-range.

oss_mixer_device.get_recsrc()

This method returns a bitmask indicating which control(s) are currently being used as a recording source.

oss_mixer_device.set_recsrc(*bitmask*)

Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises **`OSError`** if an invalid source was specified. To set the current recording source to the microphone input:

```
mixer.setrecsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```

`pipes` — Interface to shell pipelines

Source code: Lib/pipes.py [https://github.com/python/cpython/tree/3.11/Lib/pipes.py]

Deprecated since version 3.11, will be removed in version 3.13: The `pipes` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#pipes] for details). Please use the `subprocess` module instead.

The `pipes` module defines a class to abstract the concept of a *pipeline* — a sequence of converters from one file to another.

Because the module uses **/bin/sh** command lines, a POSIX or compatible shell for `os.system()` and `os.popen()` is required.

Availability: Unix, not VxWorks.

The `pipes` module defines the following class:

class pipes.Template

An abstraction of a pipeline.

Example:

```
>>> import pipes
>>> t = pipes.Template()
>>> t.append('tr a-z A-Z', '--')
>>> f = t.open('pipefile', 'w')
>>> f.write('hello world')
>>> f.close()
>>> open('pipefile').read()
'HELLO WORLD'
```

Template Objects

Template objects following methods:

Template.reset()

Restore a pipeline template to its initial state.

Template.clone()

Return a new, equivalent, pipeline template.

Template.debug(*flag*)

If *flag* is true, turn debugging on. Otherwise, turn debugging off. When debugging is on, commands to be executed are printed, and the shell is given `set -x` command to be more verbose.

Template.append(*cmd*, *kind*)

Append a new action at the end. The *cmd* variable must be a valid bourne shell command. The *kind* variable consists of two letters.

The first letter can be either of `'-'` (which means the command reads its standard input), `'f'` (which means the commands reads a given file on the command line) or `'.'` (which means the commands reads no input, and hence must be first.)

Similarly, the second letter can be either of `'-'` (which means the command writes to standard output), `'f'` (which means the command writes a file on the command line) or `'.'` (which means the command does not write anything, and hence must be last.)

Template.prepend(*cmd*, *kind*)

Add a new action at the beginning. See **`append()`** for explanations of the arguments.

Template.open(*file*, *mode*)

Return a file-like object, open to *file*, but read from or written to by the pipeline. Note that only one of `'r'`, `'w'` may be given.

Template.copy(*infile*, *outfile*)

Copy *infile* to *outfile* through the pipe.

`smtpd` — SMTP Server

Source code: Lib/smtpd.py [https://github.com/python/cpython/tree/3.11/Lib/smtpd.py]

This module offers several classes to implement SMTP (email) servers.

Deprecated since version 3.6, will be removed in version 3.12: The **`smtpd`** module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#smtpd] for details). The aiosmtpd [https://aiosmtpd.readthedocs.io/] package is a recommended replacement for this module. It is based on **`asyncio`** and provides a more straightforward API.

Several server implementations are present; one is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.

Additionally the SMTPChannel may be extended to implement very specific interaction behaviour with SMTP clients.

The code supports **RFC 5321** [https://datatracker.ietf.org/doc/html/rfc5321.html], plus the **RFC 1870** [https://datatracker.ietf.org/doc/html/rfc1870.html] SIZE and **RFC 6531** [https://datatracker.ietf.org/doc/html/rfc6531.html] SMTPUTF8 extensions.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

SMTPServer Objects

class smtpd.SMTPServer(*localaddr*, *remoteaddr*, *data_size_limit*=*33554432*, *map*=*None*, *enable_SMTPUTF8*=*False*, *decode_data*=*False*)

Create a new **SMTPServer** object, which binds to local address *localaddr*. It will treat *remoteaddr* as an upstream SMTP relayer. Both *localaddr* and *remoteaddr* should be a (host, port) tuple. The object inherits from **asyncore.dispatcher**, and so will insert itself into **asyncore**'s event loop on instantiation.

data_size_limit specifies the maximum number of bytes that will be accepted in a `DATA` command. A value of `None` or `0` means no limit.

map is the socket map to use for connections (an initially empty dictionary is a suitable value). If not specified the **asyncore** global socket map is used.

enable_SMTPUTF8 determines whether the `SMTPUTF8` extension (as defined in **RFC 6531** [https://datatracker.ietf.org/doc/html/rfc6531.html]) should be enabled. The default is `False`. When `True`, `SMTPUTF8` is accepted as a parameter to the `MAIL` command and when present is passed to **process_message()** in the `kwargs['mail_options']` list. *decode_data* and *enable_SMTPUTF8* cannot be set to `True` at the same time.

decode_data specifies whether the data portion of the SMTP transaction should be decoded using UTF-8. When *decode_data* is `False` (the default), the server advertises the `8BITMIME` extension (**RFC 6152** [https://datatracker.ietf.org/doc/html/rfc6152.html]), accepts the `BODY=8BITMIME` parameter to the `MAIL` command, and when present passes it to **process_message()** in the `kwargs['mail_options']` list. *decode_data* and *enable_SMTPUTF8* cannot be set to `True` at the same time.

process_message(*peer*, *mailfrom*, *rcpttos*, *data*, ***kwargs*)

Raise a **NotImplementedError** exception. Override this in subclasses to do something useful with this

message. Whatever was passed in the constructor as *remoteaddr* will be available as the **`_remoteaddr`** attribute. *peer* is the remote host's address, *mailfrom* is the envelope originator, *rcpttos* are the envelope recipients and *data* is a string containing the contents of the e-mail (which should be in **RFC 5321** [https://datatracker.ietf.org/doc/html/rfc5321.html] format).

If the *decode_data* constructor keyword is set to `True`, the *data* argument will be a unicode string. If it is set to `False`, it will be a bytes object.

kwargs is a dictionary containing additional information. It is empty if `decode_data=True` was given as an init argument, otherwise it contains the following keys:

mail_options:
: a list of all received parameters to the `MAIL` command (the elements are uppercase strings; example: `['BODY=8BITMIME', 'SMTPUTF8']`).

rcpt_options:
: same as *mail_options* but for the `RCPT` command. Currently no `RCPT TO` options are supported, so for now this will always be an empty list.

Implementations of `process_message` should use the `**kwargs` signature to accept arbitrary keyword arguments, since future feature enhancements may add keys to the kwargs dictionary.

Return `None` to request a normal `250 Ok` response; otherwise return the desired response string in **RFC 5321** [https://datatracker.ietf.org/doc/html/rfc5321.html] format.

channel_class

Override this in subclasses to use a custom **SMTPChannel** for managing SMTP clients.

New in version 3.4: The *map* constructor argument.

Changed in version 3.5: localaddr and *remoteaddr* may now contain IPv6 addresses.

New in version 3.5: The *decode_data* and *enable_SMTPUTF8* constructor parameters, and the *kwargs* parameter to **process_message()** when *decode_data* is `False`.

Changed in version 3.6: decode_data is now `False` by default.

DebuggingServer Objects

class smtpd.DebuggingServer(*localaddr*, *remoteaddr*)

Create a new debugging server. Arguments are as per **SMTPServer**. Messages will be discarded, and printed on stdout.

PureProxy Objects

class smtpd.PureProxy(*localaddr*, *remoteaddr*)

Create a new pure proxy server. Arguments are as per **SMTPServer**. Everything will be relayed to *remoteaddr*. Note that running this has a good chance to make you into an open relay, so please be careful.

SMTPChannel Objects

class smtpd.SMTPChannel(*server*, *conn*, *addr*, *data_size_limit*=*33554432*, *map*=*None*, *enable_SMTPUTF8*=*False*, *decode_data*=*False*)

Create a new **SMTPChannel** object which manages the communication between the server and a single SMTP client.

conn and *addr* are as per the instance variables described below.

data_size_limit specifies the maximum number of bytes that will be accepted in a `DATA` command. A value of `None` or `0` means no limit.

enable_SMTPUTF8 determines whether the `SMTPUTF8` extension (as defined in **RFC 6531** [https://datatracker.ietf.org/doc/html/rfc6531.html]) should be enabled. The default is `False`. *decode_data* and *enable_SMTPUTF8* cannot be set to `True` at the same time.

A dictionary can be specified in *map* to avoid using a global socket map.

decode_data specifies whether the data portion of the SMTP transaction should be decoded using UTF-8. The default is `False`. *decode_data* and *enable_SMTPUTF8* cannot be set to `True` at the same time.

To use a custom SMTPChannel implementation you need to override the **`SMTPServer.channel_class`** of your **`SMTPServer`**.

Changed in version 3.5: The *decode_data* and *enable_SMTPUTF8* parameters were added.

Changed in version 3.6: decode_data is now `False` by default.

The **`SMTPChannel`** has the following instance variables:

smtp_server
: Holds the **`SMTPServer`** that spawned this channel.

conn
: Holds the socket object connecting to the client.

addr
: Holds the address of the client, the second value returned by **`socket.accept`**

received_lines

Holds a list of the line strings (decoded using UTF-8) received from the client. The lines have their `"\r\n"` line ending translated to `"\n"`.

smtp_state

Holds the current state of the channel. This will be either **`COMMAND`** initially and then **`DATA`** after the client sends a “DATA” line.

seen_greeting

Holds a string containing the greeting sent by the client in its “HELO”.

mailfrom

Holds a string containing the address identified in the “MAIL FROM:” line from the client.

rcpttos

Holds a list of strings containing the addresses identified in the “RCPT TO:” lines from the client.

received_data

Holds a string containing all of the data sent by the client during the DATA state, up to but not including the terminating `"\r\n.\r\n"`.

fqdn

Holds the fully qualified domain name of the server as returned by **`socket.getfqdn()`**.

peer

Holds the name of the client peer as returned by `conn.getpeername()` where `conn` is **`conn`**.

The **`SMTPChannel`** operates by invoking methods named `smtp_<command>` upon reception of a command line from

the client. Built into the base **SMTPChannel** class are methods for handling the following commands (and responding to them appropriately):

Command	Action taken
HELO	Accepts the greeting from the client and stores it in **seen_greeting**. Sets server to base command mode.
EHLO	Accepts the greeting from the client and stores it in **seen_greeting**. Sets server to extended command mode.
NOOP	Takes no action.
QUIT	Closes the connection cleanly.
MAIL	Accepts the "MAIL FROM:" syntax and stores the supplied address as **mailfrom**. In extended command mode, accepts the RFC 1870 SIZE attribute and responds appropriately based on the value of *data_size_limit*.
RCPT	Accepts the "RCPT TO:" syntax and stores the supplied addresses in the **rcpttos** list.
RSET	Resets the **mailfrom**, **rcpttos**, and **received_data**, but not the greeting.
DATA	Sets the internal state to **DATA** and stores remaining lines from the client in **received_data** until the terminator `"\r\n.\r\n"` is received.
HELP	Returns minimal information on command syntax
VRFY	Returns code 252 (the server doesn't know if the address is valid)
EXPN	Reports that the command is not implemented.

`sndhdr` — Determine type of sound file

Source code: Lib/sndhdr.py [https://github.com/python/cpython/tree/3.11/Lib/sndhdr.py]

Deprecated since version 3.11, will be removed in version 3.13: The `sndhdr` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#sndhdr] for details and alternatives).

The `sndhdr` provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a `namedtuple()`, containing five attributes: (`filetype`, `framerate`, `nchannels`, `nframes`, `sampwidth`). The value for *type* indicates the data type and will be one of the strings `'aifc'`, `'aiff'`, `'au'`, `'hcom'`, `'sndr'`, `'sndt'`, `'voc'`, `'wav'`, `'8svx'`, `'sb'`, `'ub'`, or `'ul'`. The *sampling_rate* will be either the actual value or `0` if unknown or difficult to decode. Similarly, *channels* will be either the number of channels or `0` if it cannot be determined or if the value is difficult to decode. The value for *frames* will be either the number of frames or `-1`. The last item in the tuple, *bits_per_sample*, will either be the sample size in bits or `'A'` for A-LAW or `'U'` for u-LAW.

sndhdr.what(*filename*)

Determines the type of sound data stored in the file *filename* using `whathdr()`. If it succeeds, returns a namedtuple as described above, otherwise `None` is returned.

Changed in version 3.5: Result changed from a tuple to a namedtuple.

sndhdr.whathdr(*filename*)

Determines the type of sound data stored in a file based on the file header. The name of the file is given by *filename*. This function returns a namedtuple as described above on success, or `None`.

Changed in version 3.5: Result changed from a tuple to a namedtuple.

The following sound header types are recognized, as listed below with the return value from **`whathdr()`**: and **`what()`**:

Value	Sound header format
'aifc'	Compressed Audio Interchange Files
'aiff'	Audio Interchange Files
'au'	Au Files
'hcom'	HCOM Files
'sndt'	Sndtool Sound Files
'voc'	Creative Labs Audio Files
'wav'	Waveform Audio File Format Files
'8svx'	8-Bit Sampled Voice Files
'sb'	Signed Byte Audio Data Files
'ub'	UB Files
'ul'	uLAW Audio Files

sndhdr.tests

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When **`what()`** is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```
>>> import sndhdr
>>> imghdr.what('bass.wav')
'wav'
>>> imghdr.whathdr('bass.wav')
'wav'
```

spwd — The shadow password database

Deprecated since version 3.11, will be removed in version 3.13: The spwd module is deprecated (see PEP 594 [https://peps.python.org/pep-0594/#spwd] for details and alternatives).

This module provides access to the Unix shadow password database. It is available on various Unix versions.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

You must have enough privileges to access the shadow password database (this usually means you have to be root).

Shadow password database entries are reported as a tuple-like object, whose attributes correspond to the members of the `spwd` structure (Attribute field below, see `<shadow.h>`):

Index	Attribute	Meaning
0	sp_namp	Login name
1	sp_pwdp	Encrypted password
2	sp_lstchg	Date of last change
3	sp_min	Minimal number of days between changes
4	sp_max	Maximum number of days between changes
5	sp_warn	Number of days before password expires to warn user about it
6	sp_inact	Number of days after password expires until account is disabled
7	sp_expire	Number of days since 1970-01-01 when account expires
8	sp_flag	Reserved

The sp_namp and sp_pwdp items are strings, all others are integers. **KeyError** is raised if the entry asked for cannot be found.

The following functions are defined:

spwd.getspnam(*name*)

Return the shadow password database entry for the given user name.

Changed in version 3.6: Raises a **PermissionError** instead of **KeyError** if the user doesn't have privileges.

spwd.getspall()

Return a list of all available shadow password database entries, in arbitrary order.

See also

Module grp
An interface to the group database, similar to this.

Module pwd
An interface to the normal password database, similar to this.

`sunau` — Read and write Sun AU files

Source code: Lib/sunau.py [https://github.com/python/cpython/tree/3.11/Lib/sunau.py]

Deprecated since version 3.11, will be removed in version 3.13: The `sunau` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#sunau] for details).

The `sunau` module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules `aifc` and `wave`.

An audio file consists of a header followed by the data. The fields of the header are:

Field	Contents
magic word	The four bytes `.snd`.
header size	Size of the header, including info, in bytes.
data size	Physical size of the data, in bytes.
encoding	Indicates how the audio samples are encoded.
sample rate	The sampling rate.
# channels	The number of channels in the samples.
info	ASCII string giving a description of the audio file (padded with null bytes).

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The `sunau` module defines the following functions:

sunau.open(*file*, *mode*)

If *file* is a string, open the file by that name, otherwise treat it as a seekable file-like object. *mode* can be any of

`'r'`
: Read only mode.

`'w'`
: Write only mode.

Note that it does not allow read/write files.

A *mode* of `'r'` returns an **AU_read** object, while a *mode* of `'w'` or `'wb'` returns an **AU_write** object.

The **sunau** module defines the following exception:

exception sunau.Error
: An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The **sunau** module defines the following data items:

sunau.AUDIO_FILE_MAGIC
: An integer every valid Sun AU file begins with, stored in big-endian form. This is the string `.snd` interpreted as an integer.

sunau.AUDIO_FILE_ENCODING_MULAW_8
sunau.AUDIO_FILE_ENCODING_LINEAR_8
sunau.AUDIO_FILE_ENCODING_LINEAR_16
sunau.AUDIO_FILE_ENCODING_LINEAR_24
sunau.AUDIO_FILE_ENCODING_LINEAR_32
sunau.AUDIO_FILE_ENCODING_ALAW_8
: Values of the encoding field from the AU header which are supported by this module.

sunau.AUDIO_FILE_ENCODING_FLOAT
sunau.AUDIO_FILE_ENCODING_DOUBLE
sunau.AUDIO_FILE_ENCODING_ADPCM_G721
sunau.AUDIO_FILE_ENCODING_ADPCM_G722
sunau.AUDIO_FILE_ENCODING_ADPCM_G723_3
sunau.AUDIO_FILE_ENCODING_ADPCM_G723_5

Additional known values of the encoding field from the AU header, but which are not supported by this module.

AU_read Objects

AU_read objects, as returned by **open()** above, have the following methods:

AU_read.close()

Close the stream, and make the instance unusable. (This is called automatically on deletion.)

AU_read.getnchannels()

Returns number of audio channels (1 for mono, 2 for stereo).

AU_read.getsampwidth()

Returns sample width in bytes.

AU_read.getframerate()

Returns sampling frequency.

AU_read.getnframes()

Returns number of audio frames.

AU_read.getcomptype()

Returns compression type. Supported compression types are `'ULAW'`, `'ALAW'` and `'NONE'`.

AU_read.getcompname()

Human-readable version of **getcomptype()**. The supported types have the respective names `'CCITT G.711 u-law'`, `'CCITT G.711 A-law'` and `'not compressed'`.

AU_read.getparams()

Returns a **namedtuple()** `(nchannels, sampwidth,`

`framerate, nframes, comptype, compname)`, equivalent to output of the **`get*()`** methods.

AU_read.readframes(*n*)

Reads and returns at most *n* frames of audio, as a **`bytes`** object. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

AU_read.rewind()

Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

AU_read.setpos(*pos*)

Set the file pointer to the specified position. Only values returned from **`tell()`** should be used for *pos*.

AU_read.tell()

Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the **`aifc`**, and don’t do anything interesting.

AU_read.getmarkers()

Returns `None`.

AU_read.getmark(*id*)

Raise an error.

AU_write Objects

AU_write objects, as returned by **`open()`** above, have the following methods:

AU_write.setnchannels(*n*)

Set the number of channels.

AU_write.setsampwidth(*n*)

Set the sample width (in bytes.)

Changed in version 3.4: Added support for 24-bit samples.

AU_write.setframerate(*n*)

Set the frame rate.

AU_write.setnframes(*n*)

Set the number of frames. This can be later changed, when and if more frames are written.

AU_write.setcomptype(*type*, *name*)

Set the compression type and description. Only `'NONE'` and `'ULAW'` are supported on output.

AU_write.setparams(*tuple*)

The *tuple* should be `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, with values valid for the **`set*()`** methods. Set all parameters.

AU_write.tell()

Return current position in the file, with the same disclaimer for the **`AU_read.tell()`** and **`AU_read.setpos()`** methods.

AU_write.writeframesraw(*data*)

Write audio frames, without correcting *nframes*.

Changed in version 3.4: Any bytes-like object is now accepted.

AU_write.writeframes(*data*)

Write audio frames and make sure *nframes* is correct.

Changed in version 3.4: Any bytes-like object is now accepted.

AU_write.close()

Make sure *nframes* is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling **`writeframes()`** or **`writeframesraw()`**.

telnetlib — Telnet client

Source code: Lib/telnetlib.py [https://github.com/python/cpython/tree/3.11/Lib/telnetlib.py]

Deprecated since version 3.11, will be removed in version 3.13: The **telnetlib** module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#telnetlib] for details and alternatives).

The **telnetlib** module provides a **Telnet** class that implements the Telnet protocol. See **RFC 854** [https://datatracker.ietf.org/doc/html/rfc854.html] for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in `arpa/telnet.h`, with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in `arpa/telnet.h`, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

class telnetlib.Telnet(*host=None*, *port=0*[, *timeout*])

> **Telnet** represents a connection to a Telnet server. The instance is initially not connected by default; the **open()** method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the

constructor too, in which case the connection to the server will be established before the constructor returns. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not reopen an already connected instance.

This class has many **read_*()** methods. Note that some of them raise **EOFError** when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

A **Telnet** object is a context manager and can be used in a **with** statement. When the **with** block ends, the **close()** method is called:

```
>>> from telnetlib import Telnet
>>> with Telnet('localhost', 23) as tn:
...     tn.interact()
...
```

Changed in version 3.6: Context manager support added

See also

RFC 854 **[https://datatracker.ietf.org/doc/html/rfc854.html]** **- Telnet Protocol Specification**
Definition of the Telnet protocol.

Telnet Objects

Telnet instances have the following methods:

Telnet.read_until(*expected*, *timeout*=*None*)

Read until a given byte string, *expected*, is encountered or until *timeout* seconds have passed.

When no match is found, return whatever is available instead,

possibly empty bytes. Raise **EOFError** if the connection is closed and no cooked data is available.

Telnet.read_all()

Read all data until EOF as bytes; block until connection closed.

Telnet.read_some()

Read at least one byte of cooked data unless EOF is hit. Return `b''` if EOF is hit. Block if no data is immediately available.

Telnet.read_very_eager()

Read everything that can be without blocking in I/O (eager).

Raise **EOFError** if connection closed and no cooked data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.read_eager()

Read readily available data.

Raise **EOFError** if connection closed and no cooked data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.read_lazy()

Process and return data already in the queues (lazy).

Raise **EOFError** if connection closed and no data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.read_very_lazy()

Return any data available in the cooked queue (very lazy).

Raise **EOFError** if connection closed and no data available.

Return `b''` if no cooked data available otherwise. This method never blocks.

Telnet.read_sb_data()

Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a `SE` command. This method never blocks.

Telnet.open(*host*, *port=0*[, *timeout*])

Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

Raises an auditing event `telnetlib.Telnet.open` with arguments `self`, `host`, `port`.

Telnet.msg(*msg*, **args*)

Print a debug message when the debug level is `>` 0. If extra arguments are present, they are substituted in the message using the standard string formatting operator.

Telnet.set_debuglevel(*debuglevel*)

Set the debug level. The higher the value of *debuglevel*, the more debug output you get (on `sys.stdout`).

Telnet.close()

Close the connection.

Telnet.get_socket()

Return the socket object used internally.

Telnet.fileno()

Return the file descriptor of the socket object used internally.

Telnet.write(*buffer*)

Write a byte string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise **OSError** if the connection is closed.

Raises an auditing event `telnetlib.Telnet.write` with arguments `self`, `buffer`.

Changed in version 3.3: This method used to raise **socket.error**, which is now an alias of **OSError**.

Telnet.interact()

Interaction function, emulates a very dumb Telnet client.

Telnet.mt_interact()

Multithreaded version of **interact()**.

Telnet.expect(*list*, *timeout*=*None*)

Read until one from a list of a regular expressions matches.

The first argument is a list of regular expressions, either compiled (regex objects) or uncompiled (byte strings). The optional second argument is a timeout, in seconds; the default is to block indefinitely.

Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the bytes read up till and including the match.

If end of file is found and no bytes were read, raise **EOFError**. Otherwise, when nothing matches, return `(-1, None, data)` where *data* is the bytes received so far (may be empty bytes if a timeout happened).

If a regular expression ends with a greedy match (such as `.*`) or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O

timing.

Telnet.set_option_negotiation_callback(*callback*)

Each time a telnet option is read on the input flow, this *callback* (if set) is called with the following parameters: callback(telnet socket, command (DO/DONT/WILL/WONT), option). No other action is done afterwards by telnetlib.

Telnet Example

A simple example illustrating typical use:

```
import getpass
import telnetlib

HOST = "localhost"
user = input("Enter your remote account: ")
password = getpass.getpass()

tn = telnetlib.Telnet(HOST)

tn.read_until(b"login: ")
tn.write(user.encode('ascii') + b"\n")
if password:
    tn.read_until(b"Password: ")
    tn.write(password.encode('ascii') + b"\n")

tn.write(b"ls\n")
tn.write(b"exit\n")

print(tn.read_all().decode('ascii'))
```

uu — Encode and decode uuencode files

Source code: Lib/uu.py [https://github.com/python/cpython/tree/3.11/Lib/uu.py]

Deprecated since version 3.11, will be removed in version 3.13: The `uu` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#uu-and-the-uu-encoding] for details). `base64` is a modern alternative.

This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will be opened for reading and writing; the pathname `'-'` is understood to mean the standard input or output. However, this interface is deprecated; it's better for the caller to open the file itself, and be sure that, when required, the mode is `'rb'` or `'wb'` on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

The `uu` module defines the following functions:

uu.encode(*in_file*, *out_file*, *name*=*None*, *mode*=*None*, ***, *backtick*=*False*)

Uuencode file *in_file* into file *out_file*. The uuencoded file will have the header specifying *name* and *mode* as the defaults for the results of decoding the file. The default defaults are taken from *in_file*, or `'-'` and `0o666` respectively. If *backtick* is true, zeros are represented by `'`'` instead of spaces.

Changed in version 3.7: Added the *backtick* parameter.

uu.decode(*in_file*, *out_file*=*None*, *mode*=*None*, *quiet*=*False*)

This call decodes uuencoded file *in_file* placing the result on file *out_file*. If *out_file* is a pathname, *mode* is used to set the permission bits if the file must be created. Defaults for *out_file* and *mode* are taken from the uuencode header. However, if the file specified in the header already exists, a **uu.Error** is raised.

decode() may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting *quiet* to a true value silences this warning.

exception uu.Error

Subclass of **Exception**, this can be raised by **uu.decode()** under various situations, such as described above, but also including a badly formatted header, or truncated input file.

See also

Module binascii

Support module containing ASCII-to-binary and binary-to-ASCII conversions.

`xdrlib` — Encode and decode XDR data

Source code: Lib/xdrlib.py [https://github.com/python/cpython/tree/3.11/Lib/xdrlib.py]

Deprecated since version 3.11, will be removed in version 3.13: The `xdrlib` module is deprecated (see **PEP 594** [https://peps.python.org/pep-0594/#xdrlib] for details).

The `xdrlib` module supports the External Data Representation Standard as described in **RFC 1014** [https://datatracker.ietf.org/doc/html/rfc1014.html], written by Sun Microsystems, Inc. June 1987. It supports most of the data types described in the RFC.

The `xdrlib` module defines two classes, one for packing variables into XDR representation, and another for unpacking from XDR representation. There are also two exception classes.

class xdrlib.Packer

> `Packer` is the class for packing data into XDR representation. The `Packer` class is instantiated with no arguments.

class xdrlib.Unpacker(*data*)

> `Unpacker` is the complementary class which unpacks XDR data values from a string buffer. The input buffer is given as *data*.

See also

RFC 1014 [https://datatracker.ietf.org/doc/html/rfc1014.html] - XDR: External Data Representation Standard

> This RFC defined the encoding of data which was XDR at

the time this module was originally written. It has apparently been obsoleted by **RFC 1832** [https://datatracker.ietf.org/doc/html/rfc1832.html].

RFC 1832 [https://datatracker.ietf.org/doc/html/rfc1832.html] - XDR: External Data Representation Standard
Newer RFC that provides a revised definition of XDR.

Packer Objects

`Packer` instances have the following methods:

Packer.get_buffer()
Returns the current pack buffer as a string.

Packer.reset()
Resets the pack buffer to the empty string.

In general, you can pack any of the most common XDR data types by calling the appropriate `pack_type()` method. Each method takes a single argument, the value to pack. The following simple data type packing methods are supported: **`pack_uint()`**, **`pack_int()`**, **`pack_enum()`**, **`pack_bool()`**, **`pack_uhyper()`**, and **`pack_hyper()`**.

Packer.pack_float(*value*)
Packs the single-precision floating point number *value*.

Packer.pack_double(*value*)
Packs the double-precision floating point number *value*.

The following methods support packing strings, bytes, and opaque data:

Packer.pack_fstring(*n*, *s*)
Packs a fixed length string, *s*. *n* is the length of the string but it is *not* packed into the data buffer. The string is padded with

null bytes if necessary to guaranteed 4 byte alignment.

Packer.pack_fopaque(*n*, *data*)

Packs a fixed length opaque data stream, similarly to **pack_fstring()**.

Packer.pack_string(*s*)

Packs a variable length string, *s*. The length of the string is first packed as an unsigned integer, then the string data is packed with **pack_fstring()**.

Packer.pack_opaque(*data*)

Packs a variable length opaque data string, similarly to **pack_string()**.

Packer.pack_bytes(*bytes*)

Packs a variable length byte stream, similarly to **pack_string()**.

The following methods support packing arrays and lists:

Packer.pack_list(*list*, *pack_item*)

Packs a *list* of homogeneous items. This method is useful for lists with an indeterminate size; i.e. the size is not available until the entire list has been walked. For each item in the list, an unsigned integer `1` is packed first, followed by the data value from the list. *pack_item* is the function that is called to pack the individual item. At the end of the list, an unsigned integer `0` is packed.

For example, to pack a list of integers, the code might appear like this:

```
import xdrlib
p = xdrlib.Packer()
p.pack_list([1, 2, 3], p.pack_int)
```

Packer.pack_farray(*n*, *array*, *pack_item*)

Packs a fixed length list (*array*) of homogeneous items. *n* is the length of the list; it is *not* packed into the buffer, but a **ValueError** exception is raised if `len(array)` is not equal to *n*. As above, *pack_item* is the function used to pack each element.

Packer.pack_array(*list*, *pack_item*)

Packs a variable length *list* of homogeneous items. First, the length of the list is packed as an unsigned integer, then each element is packed as in **pack_farray()** above.

Unpacker Objects

The **Unpacker** class offers the following methods:

Unpacker.reset(*data*)

Resets the string buffer with the given *data*.

Unpacker.get_position()

Returns the current unpack position in the data buffer.

Unpacker.set_position(*position*)

Sets the data buffer unpack position to *position*. You should be careful about using **get_position()** and **set_position()**.

Unpacker.get_buffer()

Returns the current unpack data buffer as a string.

Unpacker.done()

Indicates unpack completion. Raises an **Error** exception if all of the data has not been unpacked.

In addition, every data type that can be packed with a **Packer**, can be unpacked with an **Unpacker**. Unpacking methods are of

the form `unpack_type()`, and take no arguments. They return the unpacked object.

Unpacker.unpack_float()

Unpacks a single-precision floating point number.

Unpacker.unpack_double()

Unpacks a double-precision floating point number, similarly to **`unpack_float()`**.

In addition, the following methods unpack strings, bytes, and opaque data:

Unpacker.unpack_fstring(*n*)

Unpacks and returns a fixed length string. *n* is the number of characters expected. Padding with null bytes to guaranteed 4 byte alignment is assumed.

Unpacker.unpack_fopaque(*n*)

Unpacks and returns a fixed length opaque data stream, similarly to **`unpack_fstring()`**.

Unpacker.unpack_string()

Unpacks and returns a variable length string. The length of the string is first unpacked as an unsigned integer, then the string data is unpacked with **`unpack_fstring()`**.

Unpacker.unpack_opaque()

Unpacks and returns a variable length opaque data string, similarly to **`unpack_string()`**.

Unpacker.unpack_bytes()

Unpacks and returns a variable length byte stream, similarly to **`unpack_string()`**.

The following methods support unpacking arrays and lists:

Unpacker.unpack_list(*unpack_item*)

Unpacks and returns a list of homogeneous items. The list is unpacked one element at a time by first unpacking an unsigned integer flag. If the flag is `1`, then the item is unpacked and appended to the list. A flag of `0` indicates the end of the list. *unpack_item* is the function that is called to unpack the items.

Unpacker.unpack_farray(*n*, *unpack_item*)

Unpacks and returns (as a list) a fixed length array of homogeneous items. *n* is number of list elements to expect in the buffer. As above, *unpack_item* is the function used to unpack each element.

Unpacker.unpack_array(*unpack_item*)

Unpacks and returns a variable length *list* of homogeneous items. First, the length of the list is unpacked as an unsigned integer, then each element is unpacked as in **`unpack_farray()`** above.

Exceptions

Exceptions in this module are coded as class instances:

exception xdrlib.Error

The base exception class. **`Error`** has a single public attribute **`msg`** containing the description of the error.

exception xdrlib.ConversionError

Class derived from **`Error`**. Contains no additional instance variables.

Here is an example of how you would catch one of these exceptions:

```
import xdrlib
p = xdrlib.Packer()
try:
```

```
    p.pack_double(8.01)
except xdrlib.ConversionError as instance:
    print('packing the double failed:', instance.msg)
```

Security Considerations

The following modules have specific security considerations:

- **base64**: base64 security considerations in **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html]
- **cgi**: CGI security considerations
- **hashlib**: all constructors take a "usedforsecurity" keyword-only argument disabling known insecure and blocked algorithms
- **http.server** is not suitable for production use, only implementing basic security checks. See the security considerations.
- **logging**: Logging configuration uses eval()
- **multiprocessing**: Connection.recv() uses pickle
- **pickle**: Restricting globals in pickle
- **random** shouldn't be used for security purposes, use **secrets** instead
- **shelve**: shelve is based on pickle and thus unsuitable for dealing with untrusted sources
- **ssl**: SSL/TLS security considerations
- **subprocess**: Subprocess security considerations
- **tempfile**: mktemp is deprecated due to vulnerability to race conditions
- **xml**: XML vulnerabilities
- **zipfile**: maliciously prepared .zip files can cause disk volume exhaustion

The **-I** command line option can be used to run Python in isolated mode. When it cannot be used, the **-P** option or the **PYTHONSAFEPATH** environment variable can be used to not prepend a potentially unsafe path to **sys.path** such as the current directory, the script's directory or an empty string.

Extending and Embedding the Python Interpreter

This document describes how to write modules in C or C++ to extend the Python interpreter with new modules. Those modules can not only define new functions but also new object types and their methods. The document also describes how to embed the Python interpreter in another application, for use as an extension language. Finally, it shows how to compile and link extension modules so that they can be loaded dynamically (at run time) into the interpreter, if the underlying operating system supports this feature.

This document assumes basic knowledge about Python. For an informal introduction to the language, see The Python Tutorial. The Python Language Reference gives a more formal definition of the language. The Python Standard Library documents the existing object types, functions and modules (both built-in and written in Python) that give the language its wide application range.

For a detailed description of the whole Python/C API, see the separate Python/C API Reference Manual.

Recommended third party tools

This guide only covers the basic tools for creating extensions provided as part of this version of CPython. Third party tools like Cython [https://cython.org/], cffi [https://cffi.readthedocs.io], SWIG [https://www.swig.org] and Numba [https://numba.pydata.org/] offer both simpler and more sophisticated approaches to creating C and C++ extensions for Python.

See also

Python Packaging User Guide: Binary Extensions **[https://packaging.python.org/guides/packaging-binary-extensions/]**

The Python Packaging User Guide not only covers several available tools that simplify the creation of binary extensions, but also discusses the various reasons why creating an extension module may be desirable in the first place.

Creating extensions without third party tools

This section of the guide covers creating C and C++ extensions without assistance from third party tools. It is intended primarily for creators of those tools, rather than being a recommended way to create your own C extensions.

Embedding the CPython runtime in a larger application

Sometimes, rather than creating an extension that runs inside the Python interpreter as the main application, it is desirable to instead embed the CPython runtime inside a larger application. This section covers some of the details involved in doing that successfully.

- 1. Embedding Python in Another Application
    - 1.1. Very High Level Embedding
    - 1.2. Beyond Very High Level Embedding: An overview
    - 1.3. Pure Embedding
    - 1.4. Extending Embedded Python
    - 1.5. Embedding Python in C++
    - 1.6. Compiling and Linking under Unix-like systems

1. Extending Python with C or C++

It is quite easy to add new built-in modules to Python, if you know how to program in C. Such *extension modules* can do two things that can't be done directly in Python: they can implement new built-in object types, and they can call C library functions and system calls.

To support extensions, the Python API (Application Programmers Interface) defines a set of functions, macros and variables that provide access to most aspects of the Python run-time system. The Python API is incorporated in a C source file by including the header `"Python.h"`.

The compilation of an extension module depends on its intended use as well as on your system setup; details are given in later chapters.

Note

The C extension interface is specific to CPython, and extension modules do not work on other Python implementations. In many cases, it is possible to avoid writing C extensions and preserve portability to other implementations. For example, if your use case is calling C library functions or system calls, you should consider using the **`ctypes`** module or the cffi [https://cffi.readthedocs.io/] library rather than writing custom C code. These modules let you write Python code to interface with C code and are more portable between implementations of Python than writing and compiling a C extension module.

1.1. A Simple Example

Let's create an extension module called `spam` (the favorite food of

Monty Python fans…) and let's say we want to create a Python interface to the C library function **`system()`** [1]. This function takes a null-terminated character string as argument and returns an integer. We want this function to be callable from Python as follows:

```
>>> import spam
>>> status = spam.system("ls -l")
```

Begin by creating a file `spammodule.c`. (Historically, if a module is called `spam`, the C file containing its implementation is called `spammodule.c`; if the module name is very long, like `spammify`, the module name can be just `spammify.c`.)

The first two lines of our file can be:

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
```

which pulls in the Python API (you can add a comment describing the purpose of the module and a copyright notice if you like).

Note

Since Python may define some pre-processor definitions which affect the standard headers on some systems, you *must* include `Python.h` before any standard headers are included.

It is recommended to always define `PY_SSIZE_T_CLEAN` before including `Python.h`. See Extracting Parameters in Extension Functions for a description of this macro.

All user-visible symbols defined by `Python.h` have a prefix of `Py` or `PY`, except those defined in standard header files. For convenience, and since they are used extensively by the Python interpreter, `"Python.h"` includes a few standard header files: `<stdio.h>`, `<string.h>`, `<errno.h>`, and `<stdlib.h>`. If the latter header file does not exist on your system, it declares the functions **`malloc()`**, **`free()`** and **`realloc()`** directly.

The next thing we add to our module file is the C function that will be called when the Python expression `spam.system(string)` is evaluated (we'll see shortly how it ends up being called):

```
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    return PyLong_FromLong(sts);
}
```

There is a straightforward translation from the argument list in Python (for example, the single expression `"ls -l"`) to the arguments passed to the C function. The C function always has two arguments, conventionally named *self* and *args*.

The *self* argument points to the module object for module-level functions; for a method it would point to the object instance.

The *args* argument will be a pointer to a Python tuple object containing the arguments. Each item of the tuple corresponds to an argument in the call's argument list. The arguments are Python objects — in order to do anything with them in our C function we have to convert them to C values. The function **`PyArg_ParseTuple()`** in the Python API checks the argument types and converts them to C values. It uses a template string to determine the required types of the arguments as well as the types of the C variables into which to store the converted values. More about this later.

`PyArg_ParseTuple()` returns true (nonzero) if all arguments have the right type and its components have been stored in the variables whose addresses are passed. It returns false (zero) if an invalid argument list was passed. In the latter case it also raises an appropriate exception so the calling function can return `NULL`

immediately (as we saw in the example).

1.2. Intermezzo: Errors and Exceptions

An important convention throughout the Python interpreter is the following: when a function fails, it should set an exception condition and return an error value (usually `-1` or a `NULL` pointer). Exception information is stored in three members of the interpreter's thread state. These are `NULL` if there is no exception. Otherwise they are the C equivalents of the members of the Python tuple returned by **`sys.exc_info()`**. These are the exception type, exception instance, and a traceback object. It is important to know about them to understand how errors are passed around.

The Python API defines a number of functions to set various types of exceptions.

The most common one is **`PyErr_SetString()`**. Its arguments are an exception object and a C string. The exception object is usually a predefined object like **`PyExc_ZeroDivisionError`**. The C string indicates the cause of the error and is converted to a Python string object and stored as the "associated value" of the exception.

Another useful function is **`PyErr_SetFromErrno()`**, which only takes an exception argument and constructs the associated value by inspection of the global variable **`errno`**. The most general function is **`PyErr_SetObject()`**, which takes two object arguments, the exception and its associated value. You don't need to **`Py_INCREF()`** the objects passed to any of these functions.

You can test non-destructively whether an exception has been set with **`PyErr_Occurred()`**. This returns the current exception object, or `NULL` if no exception has occurred. You normally don't need to call **`PyErr_Occurred()`** to see whether an error occurred in a function call, since you should be able to tell from the return value.

When a function *f* that calls another function *g* detects that the latter fails, *f* should itself return an error value (usually `NULL` or `-1`). It should *not* call one of the `PyErr_*` functions — one has

already been called by *g*. *f*'s caller is then supposed to also return an error indication to *its* caller, again *without* calling `PyErr_*`, and so on — the most detailed cause of the error was already reported by the function that first detected it. Once the error reaches the Python interpreter's main loop, this aborts the currently executing Python code and tries to find an exception handler specified by the Python programmer.

(There are situations where a module can actually give a more detailed error message by calling another `PyErr_*` function, and in such cases it is fine to do so. As a general rule, however, this is not necessary, and can cause information about the cause of the error to be lost: most operations can fail for a variety of reasons.)

To ignore an exception set by a function call that failed, the exception condition must be cleared explicitly by calling **`PyErr_Clear()`**. The only time C code should call **`PyErr_Clear()`** is if it doesn't want to pass the error on to the interpreter but wants to handle it completely by itself (possibly by trying something else, or pretending nothing went wrong).

Every failing **`malloc()`** call must be turned into an exception — the direct caller of **`malloc()`** (or **`realloc()`**) must call **`PyErr_NoMemory()`** and return a failure indicator itself. All the object-creating functions (for example, **`PyLong_FromLong()`**) already do this, so this note is only relevant to those who call **`malloc()`** directly.

Also note that, with the important exception of **`PyArg_ParseTuple()`** and friends, functions that return an integer status usually return a positive value or zero for success and `-1` for failure, like Unix system calls.

Finally, be careful to clean up garbage (by making **`Py_XDECREF()`** or **`Py_DECREF()`** calls for objects you have already created) when you return an error indicator!

The choice of which exception to raise is entirely yours. There are predeclared C objects corresponding to all built-in Python exceptions, such as **`PyExc_ZeroDivisionError`**, which you can use directly. Of course, you should choose exceptions wisely —

don't use **PyExc_TypeError** to mean that a file couldn't be opened (that should probably be **PyExc_IOError**). If something's wrong with the argument list, the **PyArg_ParseTuple()** function usually raises **PyExc_TypeError**. If you have an argument whose value must be in a particular range or must satisfy other conditions, **PyExc_ValueError** is appropriate.

You can also define a new exception that is unique to your module. For this, you usually declare a static object variable at the beginning of your file:

```
static PyObject *SpamError;
```

and initialize it in your module's initialization function (**PyInit_spam()**) with an exception object:

```
PyMODINIT_FUNC
PyInit_spam(void)
{
    PyObject *m;

    m = PyModule_Create(&spammodule);
    if (m == NULL)
        return NULL;

    SpamError = PyErr_NewException("spam.error", NULL, N
    Py_XINCREF(SpamError);
    if (PyModule_AddObject(m, "error", SpamError) < 0) {
        Py_XDECREF(SpamError);
        Py_CLEAR(SpamError);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

Note that the Python name for the exception object is **spam.error**. The **PyErr_NewException()** function may create a class with the base class being **Exception** (unless another class

is passed in instead of `NULL`), described in Built-in Exceptions.

Note also that the **`SpamError`** variable retains a reference to the newly created exception class; this is intentional! Since the exception could be removed from the module by external code, an owned reference to the class is needed to ensure that it will not be discarded, causing **`SpamError`** to become a dangling pointer. Should it become a dangling pointer, C code which raises the exception could cause a core dump or other unintended side effects.

We discuss the use of `PyMODINIT_FUNC` as a function return type later in this sample.

The **`spam.error`** exception can be raised in your extension module using a call to **`PyErr_SetString()`** as shown below:

```
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = system(command);
    if (sts < 0) {
        PyErr_SetString(SpamError, "System command faile
        return NULL;
    }
    return PyLong_FromLong(sts);
}
```

1.3. Back to the Example

Going back to our example function, you should now be able to understand this statement:

```
if (!PyArg_ParseTuple(args, "s", &command))
    return NULL;
```

It returns `NULL` (the error indicator for functions returning object pointers) if an error is detected in the argument list, relying on the exception set by **`PyArg_ParseTuple()`**. Otherwise the string value of the argument has been copied to the local variable **`command`**. This is a pointer assignment and you are not supposed to modify the string to which it points (so in Standard C, the variable **`command`** should properly be declared as `const char *command`).

The next statement is a call to the Unix function **`system()`**, passing it the string we just got from **`PyArg_ParseTuple()`**:

```
sts = system(command);
```

Our **`spam.system()`** function must return the value of **`sts`** as a Python object. This is done using the function **`PyLong_FromLong()`**.

```
return PyLong_FromLong(sts);
```

In this case, it will return an integer object. (Yes, even integers are objects on the heap in Python!)

If you have a C function that returns no useful argument (a function returning void), the corresponding Python function must return `None`. You need this idiom to do so (which is implemented by the **`Py_RETURN_NONE`** macro):

```
Py_INCREF(Py_None);
return Py_None;
```

`Py_None` is the C name for the special Python object `None`. It is a genuine Python object rather than a `NULL` pointer, which means "error" in most contexts, as we have seen.

1.4. The Module's Method Table and Initialization Function

I promised to show how **`spam_system()`** is called from Python programs. First, we need to list its name and address in a "method

table”:

```
static PyMethodDef SpamMethods[] = {
    ...
    {"system",  spam_system, METH_VARARGS,
     "Execute a shell command."},
    ...
    {NULL, NULL, 0, NULL}        /* Sentinel */
};
```

Note the third entry (`METH_VARARGS`). This is a flag telling the interpreter the calling convention to be used for the C function. It should normally always be `METH_VARARGS` or `METH_VARARGS | METH_KEYWORDS`; a value of `0` means that an obsolete variant of **`PyArg_ParseTuple()`** is used.

When using only `METH_VARARGS`, the function should expect the Python-level parameters to be passed in as a tuple acceptable for parsing via **`PyArg_ParseTuple()`**; more information on this function is provided below.

The **`METH_KEYWORDS`** bit may be set in the third field if keyword arguments should be passed to the function. In this case, the C function should accept a third `PyObject *` parameter which will be a dictionary of keywords. Use **`PyArg_ParseTupleAndKeywords()`** to parse the arguments to such a function.

The method table must be referenced in the module definition structure:

```
static struct PyModuleDef spammodule = {
    PyModuleDef_HEAD_INIT,
    "spam",   /* name of module */
    spam_doc, /* module documentation, may be NULL */
    -1,       /* size of per-interpreter state of the mo
                 or -1 if the module keeps state in glob
    SpamMethods
};
```

This structure, in turn, must be passed to the interpreter in the module's initialization function. The initialization function must be named **`PyInit_name()`**, where *name* is the name of the module, and should be the only non-`static` item defined in the module file:

```
PyMODINIT_FUNC
PyInit_spam(void)
{
    return PyModule_Create(&spammodule);
}
```

Note that PyMODINIT_FUNC declares the function as `PyObject *` return type, declares any special linkage declarations required by the platform, and for C++ declares the function as `extern "C"`.

When the Python program imports module **`spam`** for the first time, **`PyInit_spam()`** is called. (See below for comments about embedding Python.) It calls **`PyModule_Create()`**, which returns a module object, and inserts built-in function objects into the newly created module based upon the table (an array of **`PyMethodDef`** structures) found in the module definition. **`PyModule_Create()`** returns a pointer to the module object that it creates. It may abort with a fatal error for certain errors, or return `NULL` if the module could not be initialized satisfactorily. The init function must return the module object to its caller, so that it then gets inserted into `sys.modules`.

When embedding Python, the **`PyInit_spam()`** function is not called automatically unless there's an entry in the **`PyImport_Inittab`** table. To add the module to the initialization table, use **`PyImport_AppendInittab()`**, optionally followed by an import of the module:

```
int
main(int argc, char *argv[])
{
    wchar_t *program = Py_DecodeLocale(argv[0], NULL);
    if (program == NULL) {
        fprintf(stderr, "Fatal error: cannot decode argv
```

```
        exit(1);
    }

    /* Add a built-in module, before Py_Initialize */
    if (PyImport_AppendInittab("spam", PyInit_spam) == -
        fprintf(stderr, "Error: could not extend in-buil
        exit(1);
    }

    /* Pass argv[0] to the Python interpreter */
    Py_SetProgramName(program);

    /* Initialize the Python interpreter.  Required.
       If this step fails, it will be a fatal error. */
    Py_Initialize();

    /* Optionally import the module; alternatively,
       import can be deferred until the embedded script
       imports it. */
    PyObject *pmodule = PyImport_ImportModule("spam");
    if (!pmodule) {
        PyErr_Print();
        fprintf(stderr, "Error: could not import module
    }

    ...

    PyMem_RawFree(program);
    return 0;
}
```

Note

Removing entries from `sys.modules` or importing compiled modules into multiple interpreters within a process (or following a **`fork()`** without an intervening **`exec()`**) can create problems for some extension modules. Extension module authors should exercise caution when initializing internal data structures.

A more substantial example module is included in the Python source distribution as `Modules/xxmodule.c`. This file may be used as a template or simply read as an example.

Note

Unlike our `spam` example, `xxmodule` uses *multi-phase initialization* (new in Python 3.5), where a PyModuleDef structure is returned from `PyInit_spam`, and creation of the module is left to the import machinery. For details on multi-phase initialization, see **PEP 489** [https://peps.python.org/pep-0489/].

1.5. Compilation and Linkage

There are two more things to do before you can use your new extension: compiling and linking it with the Python system. If you use dynamic loading, the details may depend on the style of dynamic loading your system uses; see the chapters about building extension modules (chapter Building C and C++ Extensions) and additional information that pertains only to building on Windows (chapter Building C and C++ Extensions on Windows) for more information about this.

If you can't use dynamic loading, or if you want to make your module a permanent part of the Python interpreter, you will have to change the configuration setup and rebuild the interpreter. Luckily, this is very simple on Unix: just place your file (`spammodule.c` for example) in the `Modules/` directory of an unpacked source distribution, add a line to the file `Modules/Setup.local` describing your file:

```
spam spammodule.o
```

and rebuild the interpreter by running **make** in the toplevel directory. You can also run **make** in the `Modules/` subdirectory, but then you must first rebuild `Makefile` there by running '**make** Makefile'. (This is necessary each time you change the `Setup` file.)

If your module requires additional libraries to link with, these can

be listed on the line in the configuration file as well, for instance:

```
spam spammodule.o -lX11
```

1.6. Calling Python Functions from C

So far we have concentrated on making C functions callable from Python. The reverse is also useful: calling Python functions from C. This is especially the case for libraries that support so-called "callback" functions. If a C interface makes use of callbacks, the equivalent Python often needs to provide a callback mechanism to the Python programmer; the implementation will require calling the Python callback functions from a C callback. Other uses are also imaginable.

Fortunately, the Python interpreter is easily called recursively, and there is a standard interface to call a Python function. (I won't dwell on how to call the Python parser with a particular string as input — if you're interested, have a look at the implementation of the `-c` command line option in `Modules/main.c` from the Python source code.)

Calling a Python function is easy. First, the Python program must somehow pass you the Python function object. You should provide a function (or some other interface) to do this. When this function is called, save a pointer to the Python function object (be careful to `Py_INCREF()` it!) in a global variable — or wherever you see fit. For example, the following function might be part of a module definition:

```
static PyObject *my_callback = NULL;

static PyObject *
my_set_callback(PyObject *dummy, PyObject *args)
{
    PyObject *result = NULL;
    PyObject *temp;

    if (PyArg_ParseTuple(args, "O:set_callback", &temp))
        if (!PyCallable_Check(temp)) {
```

```
            PyErr_SetString(PyExc_TypeError, "parameter
            return NULL;
        }
        Py_XINCREF(temp);         /* Add a reference to
        Py_XDECREF(my_callback);  /* Dispose of previous
        my_callback = temp;       /* Remember new callba
        /* Boilerplate to return "None" */
        Py_INCREF(Py_None);
        result = Py_None;
    }
    return result;
}
```

This function must be registered with the interpreter using the **`METH_VARARGS`** flag; this is described in section The Module's Method Table and Initialization Function. The **`PyArg_ParseTuple()`** function and its arguments are documented in section Extracting Parameters in Extension Functions.

The macros **`Py_XINCREF()`** and **`Py_XDECREF()`** increment/decrement the reference count of an object and are safe in the presence of `NULL` pointers (but note that *temp* will not be `NULL` in this context). More info on them in section Reference Counts.

Later, when it is time to call the function, you call the C function **`PyObject_CallObject()`**. This function has two arguments, both pointers to arbitrary Python objects: the Python function, and the argument list. The argument list must always be a tuple object, whose length is the number of arguments. To call the Python function with no arguments, pass in `NULL`, or an empty tuple; to call it with one argument, pass a singleton tuple. **`Py_BuildValue()`** returns a tuple when its format string consists of zero or more format codes between parentheses. For example:

```
int arg;
PyObject *arglist;
PyObject *result;
...
arg = 123;
```

```
...
/* Time to call the callback */
arglist = Py_BuildValue("(i)", arg);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);
```

PyObject_CallObject() returns a Python object pointer: this is the return value of the Python function. **PyObject_CallObject()** is "reference-count-neutral" with respect to its arguments. In the example a new tuple was created to serve as the argument list, which is **Py_DECREF()**-ed immediately after the **PyObject_CallObject()** call.

The return value of **PyObject_CallObject()** is "new": either it is a brand new object, or it is an existing object whose reference count has been incremented. So, unless you want to save it in a global variable, you should somehow **Py_DECREF()** the result, even (especially!) if you are not interested in its value.

Before you do this, however, it is important to check that the return value isn't `NULL`. If it is, the Python function terminated by raising an exception. If the C code that called **PyObject_CallObject()** is called from Python, it should now return an error indication to its Python caller, so the interpreter can print a stack trace, or the calling Python code can handle the exception. If this is not possible or desirable, the exception should be cleared by calling **PyErr_Clear()**. For example:

```
if (result == NULL)
    return NULL; /* Pass error back */
...use result...
Py_DECREF(result);
```

Depending on the desired interface to the Python callback function, you may also have to provide an argument list to **PyObject_CallObject()**. In some cases the argument list is also provided by the Python program, through the same interface that specified the callback function. It can then be saved and used in the same manner as the function object. In other cases, you may have to construct a new tuple to pass as the argument list. The simplest

way to do this is to call **Py_BuildValue()**. For example, if you want to pass an integral event code, you might use the following code:

```
PyObject *arglist;
...
arglist = Py_BuildValue("(l)", eventcode);
result = PyObject_CallObject(my_callback, arglist);
Py_DECREF(arglist);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```

Note the placement of `Py_DECREF(arglist)` immediately after the call, before the error check! Also note that strictly speaking this code is not complete: **Py_BuildValue()** may run out of memory, and this should be checked.

You may also call a function with keyword arguments by using **PyObject_Call()**, which supports arguments and keyword arguments. As in the above example, we use **Py_BuildValue()** to construct the dictionary.

```
PyObject *dict;
...
dict = Py_BuildValue("{s:i}", "name", val);
result = PyObject_Call(my_callback, NULL, dict);
Py_DECREF(dict);
if (result == NULL)
    return NULL; /* Pass error back */
/* Here maybe use the result */
Py_DECREF(result);
```

1.7. Extracting Parameters in Extension Functions

The **PyArg_ParseTuple()** function is declared as follows:

```
int PyArg_ParseTuple(PyObject *arg, const char *format,
```

The *arg* argument must be a tuple object containing an argument list passed from Python to a C function. The *format* argument must be a format string, whose syntax is explained in Parsing arguments and building values in the Python/C API Reference Manual. The remaining arguments must be addresses of variables whose type is determined by the format string.

Note that while **`PyArg_ParseTuple()`** checks that the Python arguments have the required types, it cannot check the validity of the addresses of C variables passed to the call: if you make mistakes there, your code will probably crash or at least overwrite random bits in memory. So be careful!

Note that any Python object references which are provided to the caller are *borrowed* references; do not decrement their reference count!

Some example calls:

```
#define PY_SSIZE_T_CLEAN  /* Make "s#" use Py_ssize_t ra
#include <Python.h>

int ok;
int i, j;
long k, l;
const char *s;
Py_ssize_t size;

ok = PyArg_ParseTuple(args, ""); /* No arguments */
    /* Python call: f() */

ok = PyArg_ParseTuple(args, "s", &s); /* A string */
    /* Possible Python call: f('whoops!') */

ok = PyArg_ParseTuple(args, "lls", &k, &l, &s); /* Two l
    /* Possible Python call: f(1, 2, 'three') */

ok = PyArg_ParseTuple(args, "(ii)s#", &i, &j, &s, &size)
    /* A pair of ints and a string, whose size is also r
```

```
    /* Possible Python call: f((1, 2), 'three') */

{
    const char *file;
    const char *mode = "r";
    int bufsize = 0;
    ok = PyArg_ParseTuple(args, "s|si", &file, &mode, &b
    /* A string, and optionally another string and an in
    /* Possible Python calls:
       f('spam')
       f('spam', 'w')
       f('spam', 'wb', 100000) */
}

{
    int left, top, right, bottom, h, v;
    ok = PyArg_ParseTuple(args, "((ii)(ii))(ii)",
             &left, &top, &right, &bottom, &h, &v);
    /* A rectangle and a point */
    /* Possible Python call:
       f(((0, 0), (400, 300)), (10, 10)) */
}

{
    Py_complex c;
    ok = PyArg_ParseTuple(args, "D:myfunction", &c);
    /* a complex, also providing a function name for err
    /* Possible Python call: myfunction(1+2j) */
}
```

1.8. Keyword Parameters for Extension Functions

The **PyArg_ParseTupleAndKeywords()** function is declared as follows:

```
int PyArg_ParseTupleAndKeywords(PyObject *arg, PyObject
                                const char *format, char
```

The *arg* and *format* parameters are identical to those of the **PyArg_ParseTuple()** function. The *kwdict* parameter is the dictionary of keywords received as the third parameter from the Python runtime. The *kwlist* parameter is a `NULL`-terminated list of strings which identify the parameters; the names are matched with the type information from *format* from left to right. On success, **PyArg_ParseTupleAndKeywords()** returns true, otherwise it returns false and raises an appropriate exception.

Note

Nested tuples cannot be parsed when using keyword arguments! Keyword parameters passed in which are not present in the *kwlist* will cause **TypeError** to be raised.

Here is an example module which uses keywords, based on an example by Geoff Philbrick (philbrick@hks.com):

```
#define PY_SSIZE_T_CLEAN  /* Make "s#" use Py_ssize_t ra
#include <Python.h>

static PyObject *
keywdarg_parrot(PyObject *self, PyObject *args, PyObject
{
    int voltage;
    const char *state = "a stiff";
    const char *action = "voom";
    const char *type = "Norwegian Blue";

    static char *kwlist[] = {"voltage", "state", "actior

    if (!PyArg_ParseTupleAndKeywords(args, keywds, "i|ss
                                     &voltage, &state, &
        return NULL;

    printf("-- This parrot wouldn't %s if you put %i Vol
           action, voltage);
    printf("-- Lovely plumage, the %s -- It's %s!\n", ty
```

```
    Py_RETURN_NONE;
}

static PyMethodDef keywdarg_methods[] = {
    /* The cast of the function is necessary since PyCFu
     * only take two PyObject* parameters, and keywdarg_
     * three.
     */
    {"parrot", (PyCFunction)(void(*)(void))keywdarg_parr
     "Print a lovely skit to standard output."},
    {NULL, NULL, 0, NULL}   /* sentinel */
};

static struct PyModuleDef keywdargmodule = {
    PyModuleDef_HEAD_INIT,
    "keywdarg",
    NULL,
    -1,
    keywdarg_methods
};

PyMODINIT_FUNC
PyInit_keywdarg(void)
{
    return PyModule_Create(&keywdargmodule);
}
```

1.9. Building Arbitrary Values

This function is the counterpart to **`PyArg_ParseTuple()`**. It is declared as follows:

```
PyObject *Py_BuildValue(const char *format, ...);
```

It recognizes a set of format units similar to the ones recognized by **`PyArg_ParseTuple()`**, but the arguments (which are input to the function, not output) must not be pointers, just values. It returns a new Python object, suitable for returning from a C function called from Python.

One difference with **PyArg_ParseTuple()**: while the latter requires its first argument to be a tuple (since Python argument lists are always represented as tuples internally), **Py_BuildValue()** does not always build a tuple. It builds a tuple only if its format string contains two or more format units. If the format string is empty, it returns `None`; if it contains exactly one format unit, it returns whatever object is described by that format unit. To force it to return a tuple of size 0 or one, parenthesize the format string.

Examples (to the left the call, to the right the resulting Python value):

```
Py_BuildValue("")                        None
Py_BuildValue("i", 123)                  123
Py_BuildValue("iii", 123, 456, 789)      (123, 456, 789)
Py_BuildValue("s", "hello")              'hello'
Py_BuildValue("y", "hello")              b'hello'
Py_BuildValue("ss", "hello", "world")    ('hello', 'worl
Py_BuildValue("s#", "hello", 4)          'hell'
Py_BuildValue("y#", "hello", 4)          b'hell'
Py_BuildValue("()")                      ()
Py_BuildValue("(i)", 123)                (123,)
Py_BuildValue("(ii)", 123, 456)          (123, 456)
Py_BuildValue("(i,i)", 123, 456)         (123, 456)
Py_BuildValue("[i,i]", 123, 456)         [123, 456]
Py_BuildValue("{s:i,s:i}",
              "abc", 123, "def", 456)    {'abc': 123, 'c
Py_BuildValue("((ii)(ii)) (ii)",
              1, 2, 3, 4, 5, 6)          (((1, 2), (3, 4
```

1.10. Reference Counts

In languages like C or C++, the programmer is responsible for dynamic allocation and deallocation of memory on the heap. In C, this is done using the functions **malloc()** and **free()**. In C++, the operators `new` and `delete` are used with essentially the same meaning and we'll restrict the following discussion to the C case.

Every block of memory allocated with **malloc()** should

eventually be returned to the pool of available memory by exactly one call to **`free()`**. It is important to call **`free()`** at the right time. If a block's address is forgotten but **`free()`** is not called for it, the memory it occupies cannot be reused until the program terminates. This is called a *memory leak*. On the other hand, if a program calls **`free()`** for a block and then continues to use the block, it creates a conflict with re-use of the block through another **`malloc()`** call. This is called *using freed memory*. It has the same bad consequences as referencing uninitialized data — core dumps, wrong results, mysterious crashes.

Common causes of memory leaks are unusual paths through the code. For instance, a function may allocate a block of memory, do some calculation, and then free the block again. Now a change in the requirements for the function may add a test to the calculation that detects an error condition and can return prematurely from the function. It's easy to forget to free the allocated memory block when taking this premature exit, especially when it is added later to the code. Such leaks, once introduced, often go undetected for a long time: the error exit is taken only in a small fraction of all calls, and most modern machines have plenty of virtual memory, so the leak only becomes apparent in a long-running process that uses the leaking function frequently. Therefore, it's important to prevent leaks from happening by having a coding convention or strategy that minimizes this kind of errors.

Since Python makes heavy use of **`malloc()`** and **`free()`**, it needs a strategy to avoid memory leaks as well as the use of freed memory. The chosen method is called *reference counting*. The principle is simple: every object contains a counter, which is incremented when a reference to the object is stored somewhere, and which is decremented when a reference to it is deleted. When the counter reaches zero, the last reference to the object has been deleted and the object is freed.

An alternative strategy is called *automatic garbage collection*. (Sometimes, reference counting is also referred to as a garbage collection strategy, hence my use of "automatic" to distinguish the two.) The big advantage of automatic garbage collection is that the user doesn't need to call **`free()`** explicitly. (Another claimed

advantage is an improvement in speed or memory usage — this is no hard fact however.) The disadvantage is that for C, there is no truly portable automatic garbage collector, while reference counting can be implemented portably (as long as the functions **malloc()** and **free()** are available — which the C Standard guarantees). Maybe some day a sufficiently portable automatic garbage collector will be available for C. Until then, we'll have to live with reference counts.

While Python uses the traditional reference counting implementation, it also offers a cycle detector that works to detect reference cycles. This allows applications to not worry about creating direct or indirect circular references; these are the weakness of garbage collection implemented using only reference counting. Reference cycles consist of objects which contain (possibly indirect) references to themselves, so that each object in the cycle has a reference count which is non-zero. Typical reference counting implementations are not able to reclaim the memory belonging to any objects in a reference cycle, or referenced from the objects in the cycle, even though there are no further references to the cycle itself.

The cycle detector is able to detect garbage cycles and can reclaim them. The **gc** module exposes a way to run the detector (the **collect()** function), as well as configuration interfaces and the ability to disable the detector at runtime.

1.10.1. Reference Counting in Python

There are two macros, `Py_INCREF(x)` and `Py_DECREF(x)`, which handle the incrementing and decrementing of the reference count. **Py_DECREF()** also frees the object when the count reaches zero. For flexibility, it doesn't call **free()** directly — rather, it makes a call through a function pointer in the object's *type object*. For this purpose (and others), every object also contains a pointer to its type object.

The big question now remains: when to use `Py_INCREF(x)` and `Py_DECREF(x)`? Let's first introduce some terms. Nobody "owns" an object; however, you can *own a reference* to an object. An object's

reference count is now defined as the number of owned references to it. The owner of a reference is responsible for calling `Py_DECREF()` when the reference is no longer needed. Ownership of a reference can be transferred. There are three ways to dispose of an owned reference: pass it on, store it, or call `Py_DECREF()`. Forgetting to dispose of an owned reference creates a memory leak.

It is also possible to *borrow* 2 a reference to an object. The borrower of a reference should not call `Py_DECREF()`. The borrower must not hold on to the object longer than the owner from which it was borrowed. Using a borrowed reference after the owner has disposed of it risks using freed memory and should be avoided completely 3.

The advantage of borrowing over owning a reference is that you don't need to take care of disposing of the reference on all possible paths through the code — in other words, with a borrowed reference you don't run the risk of leaking when a premature exit is taken. The disadvantage of borrowing over owning is that there are some subtle situations where in seemingly correct code a borrowed reference can be used after the owner from which it was borrowed has in fact disposed of it.

A borrowed reference can be changed into an owned reference by calling `Py_INCREF()`. This does not affect the status of the owner from which the reference was borrowed — it creates a new owned reference, and gives full owner responsibilities (the new owner must dispose of the reference properly, as well as the previous owner).

1.10.2. Ownership Rules

Whenever an object reference is passed into or out of a function, it is part of the function's interface specification whether ownership is transferred with the reference or not.

Most functions that return a reference to an object pass on ownership with the reference. In particular, all functions whose function it is to create a new object, such as `PyLong_FromLong()` and `Py_BuildValue()`, pass ownership to the receiver. Even if the object is not actually new, you still receive ownership of a new reference to that object. For instance, `PyLong_FromLong()` maintains a cache of popular values and can return a reference to a

cached item.

Many functions that extract objects from other objects also transfer ownership with the reference, for instance **PyObject_GetAttrString()**. The picture is less clear, here, however, since a few common routines are exceptions: **PyTuple_GetItem()**, **PyList_GetItem()**, **PyDict_GetItem()**, and **PyDict_GetItemString()** all return references that you borrow from the tuple, list or dictionary.

The function **PyImport_AddModule()** also returns a borrowed reference, even though it may actually create the object it returns: this is possible because an owned reference to the object is stored in `sys.modules`.

When you pass an object reference into another function, in general, the function borrows the reference from you — if it needs to store it, it will use **Py_INCREF()** to become an independent owner. There are exactly two important exceptions to this rule: **PyTuple_SetItem()** and **PyList_SetItem()**. These functions take over ownership of the item passed to them — even if they fail! (Note that **PyDict_SetItem()** and friends don't take over ownership — they are "normal.")

When a C function is called from Python, it borrows references to its arguments from the caller. The caller owns a reference to the object, so the borrowed reference's lifetime is guaranteed until the function returns. Only when such a borrowed reference must be stored or passed on, it must be turned into an owned reference by calling **Py_INCREF()**.

The object reference returned from a C function that is called from Python must be an owned reference — ownership is transferred from the function to its caller.

1.10.3. Thin Ice

There are a few situations where seemingly harmless use of a borrowed reference can lead to problems. These all have to do with implicit invocations of the interpreter, which can cause the owner of a reference to dispose of it.

The first and most important case to know about is using **`Py_DECREF()`** on an unrelated object while borrowing a reference to a list item. For instance:

```
void
bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);

    PyList_SetItem(list, 1, PyLong_FromLong(0L));
    PyObject_Print(item, stdout, 0); /* BUG! */
}
```

This function first borrows a reference to `list[0]`, then replaces `list[1]` with the value `0`, and finally prints the borrowed reference. Looks harmless, right? But it's not!

Let's follow the control flow into **`PyList_SetItem()`**. The list owns references to all its items, so when item 1 is replaced, it has to dispose of the original item 1. Now let's suppose the original item 1 was an instance of a user-defined class, and let's further suppose that the class defined a **`__del__()`** method. If this class instance has a reference count of 1, disposing of it will call its **`__del__()`** method.

Since it is written in Python, the **`__del__()`** method can execute arbitrary Python code. Could it perhaps do something to invalidate the reference to `item` in **`bug()`**? You bet! Assuming that the list passed into **`bug()`** is accessible to the **`__del__()`** method, it could execute a statement to the effect of `del list[0]`, and assuming this was the last reference to that object, it would free the memory associated with it, thereby invalidating `item`.

The solution, once you know the source of the problem, is easy: temporarily increment the reference count. The correct version of the function reads:

```
void
no_bug(PyObject *list)
{
```

```
    PyObject *item = PyList_GetItem(list, 0);

    Py_INCREF(item);
    PyList_SetItem(list, 1, PyLong_FromLong(0L));
    PyObject_Print(item, stdout, 0);
    Py_DECREF(item);
}
```

This is a true story. An older version of Python contained variants of this bug and someone spent a considerable amount of time in a C debugger to figure out why his **`__del__()`** methods would fail…

The second case of problems with a borrowed reference is a variant involving threads. Normally, multiple threads in the Python interpreter can't get in each other's way, because there is a global lock protecting Python's entire object space. However, it is possible to temporarily release this lock using the macro **`Py_BEGIN_ALLOW_THREADS`**, and to re-acquire it using **`Py_END_ALLOW_THREADS`**. This is common around blocking I/O calls, to let other threads use the processor while waiting for the I/O to complete. Obviously, the following function has the same problem as the previous one:

```
void
bug(PyObject *list)
{
    PyObject *item = PyList_GetItem(list, 0);
    Py_BEGIN_ALLOW_THREADS
    ...some blocking I/O call...
    Py_END_ALLOW_THREADS
    PyObject_Print(item, stdout, 0); /* BUG! */
}
```

1.10.4. NULL Pointers

In general, functions that take object references as arguments do not expect you to pass them `NULL` pointers, and will dump core (or cause later core dumps) if you do so. Functions that return object references generally return `NULL` only to indicate that an exception occurred. The reason for not testing for `NULL` arguments is that

functions often pass the objects they receive on to other function — if each function were to test for `NULL`, there would be a lot of redundant tests and the code would run more slowly.

It is better to test for `NULL` only at the "source:" when a pointer that may be `NULL` is received, for example, from **`malloc()`** or from a function that may raise an exception.

The macros **`Py_INCREF()`** and **`Py_DECREF()`** do not check for `NULL` pointers — however, their variants **`Py_XINCREF()`** and **`Py_XDECREF()`** do.

The macros for checking for a particular object type (`Pytype_Check()`) don't check for `NULL` pointers — again, there is much code that calls several of these in a row to test an object against various different expected types, and this would generate redundant tests. There are no variants with `NULL` checking.

The C function calling mechanism guarantees that the argument list passed to C functions (`args` in the examples) is never `NULL` — in fact it guarantees that it is always a tuple 4.

It is a severe error to ever let a `NULL` pointer "escape" to the Python user.

1.11. Writing Extensions in C++

It is possible to write extension modules in C++. Some restrictions apply. If the main program (the Python interpreter) is compiled and linked by the C compiler, global or static objects with constructors cannot be used. This is not a problem if the main program is linked by the C++ compiler. Functions that will be called by the Python interpreter (in particular, module initialization functions) have to be declared using `extern "C"`. It is unnecessary to enclose the Python header files in `extern "C" {...}` — they use this form already if the symbol `__cplusplus` is defined (all recent C++ compilers define this symbol).

1.12. Providing a C API for an Extension

Module

Many extension modules just provide new functions and types to be used from Python, but sometimes the code in an extension module can be useful for other extension modules. For example, an extension module could implement a type “collection” which works like lists without order. Just like the standard Python list type has a C API which permits extension modules to create and manipulate lists, this new collection type should have a set of C functions for direct manipulation from other extension modules.

At first sight this seems easy: just write the functions (without declaring them `static`, of course), provide an appropriate header file, and document the C API. And in fact this would work if all extension modules were always linked statically with the Python interpreter. When modules are used as shared libraries, however, the symbols defined in one module may not be visible to another module. The details of visibility depend on the operating system; some systems use one global namespace for the Python interpreter and all extension modules (Windows, for example), whereas others require an explicit list of imported symbols at module link time (AIX is one example), or offer a choice of different strategies (most Unices). And even if symbols are globally visible, the module whose functions one wishes to call might not have been loaded yet!

Portability therefore requires not to make any assumptions about symbol visibility. This means that all symbols in extension modules should be declared `static`, except for the module’s initialization function, in order to avoid name clashes with other extension modules (as discussed in section The Module’s Method Table and Initialization Function). And it means that symbols that *should* be accessible from other extension modules must be exported in a different way.

Python provides a special mechanism to pass C-level information (pointers) from one extension module to another one: Capsules. A Capsule is a Python data type which stores a pointer (void*). Capsules can only be created and accessed via their C API, but they can be passed around like any other Python object. In particular, they can be assigned to a name in an extension module’s

namespace. Other extension modules can then import this module, retrieve the value of this name, and then retrieve the pointer from the Capsule.

There are many ways in which Capsules can be used to export the C API of an extension module. Each function could get its own Capsule, or all C API pointers could be stored in an array whose address is published in a Capsule. And the various tasks of storing and retrieving the pointers can be distributed in different ways between the module providing the code and the client modules.

Whichever method you choose, it's important to name your Capsules properly. The function **PyCapsule_New()** takes a name parameter (const char*); you're permitted to pass in a `NULL` name, but we strongly encourage you to specify a name. Properly named Capsules provide a degree of runtime type-safety; there is no feasible way to tell one unnamed Capsule from another.

In particular, Capsules used to expose C APIs should be given a name following this convention:

```
modulename.attributename
```

The convenience function **PyCapsule_Import()** makes it easy to load a C API provided via a Capsule, but only if the Capsule's name matches this convention. This behavior gives C API users a high degree of certainty that the Capsule they load contains the correct C API.

The following example demonstrates an approach that puts most of the burden on the writer of the exporting module, which is appropriate for commonly used library modules. It stores all C API pointers (just one in the example!) in an array of void pointers which becomes the value of a Capsule. The header file corresponding to the module provides a macro that takes care of importing the module and retrieving its C API pointers; client modules only have to call this macro before accessing the C API.

The exporting module is a modification of the **spam** module from section A Simple Example. The function **spam.system()** does not call the C library function **system()** directly, but a function

PySpam_System(), which would of course do something more complicated in reality (such as adding “spam” to every command). This function **PySpam_System()** is also exported to other extension modules.

The function **PySpam_System()** is a plain C function, declared `static` like everything else:

```
static int
PySpam_System(const char *command)
{
    return system(command);
}
```

The function **spam_system()** is modified in a trivial way:

```
static PyObject *
spam_system(PyObject *self, PyObject *args)
{
    const char *command;
    int sts;

    if (!PyArg_ParseTuple(args, "s", &command))
        return NULL;
    sts = PySpam_System(command);
    return PyLong_FromLong(sts);
}
```

In the beginning of the module, right after the line

```
#include <Python.h>
```

two more lines must be added:

```
#define SPAM_MODULE
#include "spammodule.h"
```

The `#define` is used to tell the header file that it is being included in the exporting module, not a client module. Finally, the module’s initialization function must take care of initializing the C API pointer array:

```
PyMODINIT_FUNC
PyInit_spam(void)
{
    PyObject *m;
    static void *PySpam_API[PySpam_API_pointers];
    PyObject *c_api_object;

    m = PyModule_Create(&spammodule);
    if (m == NULL)
        return NULL;

    /* Initialize the C API pointer array */
    PySpam_API[PySpam_System_NUM] = (void *)PySpam_Syste

    /* Create a Capsule containing the API pointer array
    c_api_object = PyCapsule_New((void *)PySpam_API, "sp

    if (PyModule_AddObject(m, "_C_API", c_api_object) <
        Py_XDECREF(c_api_object);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

Note that `PySpam_API` is declared `static`; otherwise the pointer array would disappear when **`PyInit_spam()`** terminates!

The bulk of the work is in the header file `spammodule.h`, which looks like this:

```
#ifndef Py_SPAMMODULE_H
#define Py_SPAMMODULE_H
#ifdef __cplusplus
extern "C" {
#endif

/* Header file for spammodule */
```

```
/* C API functions */
#define PySpam_System_NUM 0
#define PySpam_System_RETURN int
#define PySpam_System_PROTO (const char *command)

/* Total number of C API pointers */
#define PySpam_API_pointers 1

#ifdef SPAM_MODULE
/* This section is used when compiling spammodule.c */

static PySpam_System_RETURN PySpam_System PySpam_System_

#else
/* This section is used in modules that use spammodule's

static void **PySpam_API;

#define PySpam_System \
 (*(PySpam_System_RETURN (*)PySpam_System_PROTO) PySpam_

/* Return -1 on error, 0 on success.
 * PyCapsule_Import will set an exception if there's an
 */
static int
import_spam(void)
{
    PySpam_API = (void **)PyCapsule_Import("spam._C_API"
    return (PySpam_API != NULL) ? 0 : -1;
}

#endif

#ifdef __cplusplus
}
#endif
```

```
#endif /* !defined(Py_SPAMMODULE_H) */
```

All that a client module must do in order to have access to the function **`PySpam_System()`** is to call the function (or rather macro) **`import_spam()`** in its initialization function:

```
PyMODINIT_FUNC
PyInit_client(void)
{
    PyObject *m;

    m = PyModule_Create(&clientmodule);
    if (m == NULL)
        return NULL;
    if (import_spam() < 0)
        return NULL;
    /* additional initialization can happen here */
    return m;
}
```

The main disadvantage of this approach is that the file `spammodule.h` is rather complicated. However, the basic structure is the same for each function that is exported, so it has to be learned only once.

Finally it should be mentioned that Capsules offer additional functionality, which is especially useful for memory allocation and deallocation of the pointer stored in a Capsule. The details are described in the Python/C API Reference Manual in the section Capsules and in the implementation of Capsules (files `Include/pycapsule.h` and `Objects/pycapsule.c` in the Python source code distribution).

Footnotes

1

An interface for this function already exists in the standard module **`os`** — it was chosen as a simple and straightforward

example.

2

The metaphor of “borrowing” a reference is not completely correct: the owner still has a copy of the reference.

3

Checking that the reference count is at least 1 **does not work** — the reference count itself could be in freed memory and may thus be reused for another object!

4

These guarantees don’t hold when you use the “old” style calling convention — this is still found in much existing code.

2. Defining Extension Types: Tutorial

Python allows the writer of a C extension module to define new types that can be manipulated from Python code, much like the built-in `str` and `list` types. The code for all extension types follows a pattern, but there are some details that you need to understand before you can get started. This document is a gentle introduction to the topic.

2.1. The Basics

The CPython runtime sees all Python objects as variables of type PyObject*, which serves as a "base type" for all Python objects. The `PyObject` structure itself only contains the object's reference count and a pointer to the object's "type object". This is where the action is; the type object determines which (C) functions get called by the interpreter when, for instance, an attribute gets looked up on an object, a method called, or it is multiplied by another object. These C functions are called "type methods".

So, if you want to define a new extension type, you need to create a new type object.

This sort of thing can only be explained by example, so here's a minimal, but complete, module that defines a new type named `Custom` inside a C extension module `custom`:

Note

What we're showing here is the traditional way of defining *static* extension types. It should be adequate for most uses. The C API also allows defining heap-allocated extension types using the `PyType_FromSpec()` function, which isn't covered in this

tutorial.

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>

typedef struct {
    PyObject_HEAD
    /* Type-specific fields go here. */
} CustomObject;

static PyTypeObject CustomType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT,
    .tp_new = PyType_GenericNew,
};

static PyModuleDef custommodule = {
    PyModuleDef_HEAD_INIT,
    .m_name = "custom",
    .m_doc = "Example module that creates an extension t
    .m_size = -1,
};

PyMODINIT_FUNC
PyInit_custom(void)
{
    PyObject *m;
    if (PyType_Ready(&CustomType) < 0)
        return NULL;

    m = PyModule_Create(&custommodule);
    if (m == NULL)
        return NULL;
```

```
    Py_INCREF(&CustomType);
    if (PyModule_AddObject(m, "Custom", (PyObject *) &Cu
        Py_DECREF(&CustomType);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

Now that's quite a bit to take in at once, but hopefully bits will seem familiar from the previous chapter. This file defines three things:

1. What a **`Custom` object** contains: this is the `CustomObject` struct, which is allocated once for each **`Custom`** instance.
2. How the **`Custom` type** behaves: this is the `CustomType` struct, which defines a set of flags and function pointers that the interpreter inspects when specific operations are requested.
3. How to initialize the **`custom`** module: this is the `PyInit_custom` function and the associated `custommodule` struct.

The first bit is:

```
typedef struct {
    PyObject_HEAD
} CustomObject;
```

This is what a Custom object will contain. `PyObject_HEAD` is mandatory at the start of each object struct and defines a field called `ob_base` of type **`PyObject`**, containing a pointer to a type object and a reference count (these can be accessed using the macros **`Py_TYPE`** and **`Py_REFCNT`** respectively). The reason for the macro is to abstract away the layout and to enable additional fields in debug builds.

Note

There is no semicolon above after the **`PyObject_HEAD`** macro. Be wary of adding one by accident: some compilers will complain.

Of course, objects generally store additional data besides the standard `PyObject_HEAD` boilerplate; for example, here is the definition for standard Python floats:

```
typedef struct {
    PyObject_HEAD
    double ob_fval;
} PyFloatObject;
```

The second bit is the definition of the type object.

```
static PyTypeObject CustomType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT,
    .tp_new = PyType_GenericNew,
};
```

Note

We recommend using C99-style designated initializers as above, to avoid listing all the **`PyTypeObject`** fields that you don't care about and also to avoid caring about the fields' declaration order.

The actual definition of **`PyTypeObject`** in `object.h` has many more fields than the definition above. The remaining fields will be filled with zeros by the C compiler, and it's common practice to not specify them explicitly unless you need them.

We're going to pick it apart, one field at a time:

```
PyVarObject_HEAD_INIT(NULL, 0)
```

This line is mandatory boilerplate to initialize the `ob_base` field mentioned above.

```
.tp_name = "custom.Custom",
```

The name of our type. This will appear in the default textual representation of our objects and in some error messages, for example:

```
>>> "" + custom.Custom()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: can only concatenate str (not "custom.Custom"
```

Note that the name is a dotted name that includes both the module name and the name of the type within the module. The module in this case is **`custom`** and the type is **`Custom`**, so we set the type name to **`custom.Custom`**. Using the real dotted import path is important to make your type compatible with the **`pydoc`** and **`pickle`** modules.

```
.tp_basicsize = sizeof(CustomObject),
.tp_itemsize = 0,
```

This is so that Python knows how much memory to allocate when creating new **`Custom`** instances. **`tp_itemsize`** is only used for variable-sized objects and should otherwise be zero.

Note

If you want your type to be subclassable from Python, and your type has the same **`tp_basicsize`** as its base type, you may have problems with multiple inheritance. A Python subclass of your type will have to list your type first in its **`__bases__`**, or else it will not be able to call your type's **`__new__()`** method without getting an error. You can avoid this problem by ensuring that your type has a larger value for **`tp_basicsize`** than its base type does. Most of the time, this will be true anyway, because either your base type will be **`object`**, or else you will

be adding data members to your base type, and therefore increasing its size.

We set the class flags to **Py_TPFLAGS_DEFAULT**.

```
.tp_flags = Py_TPFLAGS_DEFAULT,
```

All types should include this constant in their flags. It enables all of the members defined until at least Python 3.3. If you need further members, you will need to OR the corresponding flags.

We provide a doc string for the type in **tp_doc**.

```
.tp_doc = PyDoc_STR("Custom objects"),
```

To enable object creation, we have to provide a **tp_new** handler. This is the equivalent of the Python method **__new__()**, but has to be specified explicitly. In this case, we can just use the default implementation provided by the API function **PyType_GenericNew()**.

```
.tp_new = PyType_GenericNew,
```

Everything else in the file should be familiar, except for some code in **PyInit_custom()**:

```
if (PyType_Ready(&CustomType) < 0)
    return;
```

This initializes the **Custom** type, filling in a number of members to the appropriate default values, including **ob_type** that we initially set to NULL.

```
Py_INCREF(&CustomType);
if (PyModule_AddObject(m, "Custom", (PyObject *) &Custom
    Py_DECREF(&CustomType);
    Py_DECREF(m);
    return NULL;
}
```

This adds the type to the module dictionary. This allows us to

create **`Custom`** instances by calling the **`Custom`** class:

```
>>> import custom
>>> mycustom = custom.Custom()
```

That's it! All that remains is to build it; put the above code in a file called `custom.c` and:

```
from distutils.core import setup, Extension
setup(name="custom", version="1.0",
      ext_modules=[Extension("custom", ["custom.c"])])
```

in a file called `setup.py`; then typing

```
$ python setup.py build
```

at a shell should produce a file `custom.so` in a subdirectory; move to that directory and fire up Python — you should be able to `import custom` and play around with Custom objects.

That wasn't so hard, was it?

Of course, the current Custom type is pretty uninteresting. It has no data and doesn't do anything. It can't even be subclassed.

Note

While this documentation showcases the standard **`distutils`** module for building C extensions, it is recommended in real-world use cases to use the newer and better-maintained `setuptools` library. Documentation on how to do this is out of scope for this document and can be found in the Python Packaging User's Guide [https://packaging.python.org/tutorials/distributing-packages/].

2.2. Adding data and methods to the Basic example

Let's extend the basic example to add some data and methods. Let's

also make the type usable as a base class. We'll create a new module, **custom2** that adds these capabilities:

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;

static void
Custom_dealloc(CustomObject *self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject *) self);
}

static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
```

```
    }
    return (PyObject *) self;
}

static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL, *tmp;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|OOi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_XDECREF(tmp);
    }
    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_XDECREF(tmp);
    }
    return 0;
}

static PyMemberDef Custom_members[] = {
    {"first", T_OBJECT_EX, offsetof(CustomObject, first)
     "first name"},
    {"last", T_OBJECT_EX, offsetof(CustomObject, last),
     "last name"},
    {"number", T_INT, offsetof(CustomObject, number), 0,
     "custom number"},
    {NULL}  /* Sentinel */
```

```
};

static PyObject *
Custom_name(CustomObject *self, PyObject *Py_UNUSED(ignc
{
    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }
    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }
    return PyUnicode_FromFormat("%S %S", self->first, se
}

static PyMethodDef Custom_methods[] = {
    {"name", (PyCFunction) Custom_name, METH_NOARGS,
     "Return the name, combining the first and last name
    },
    {NULL}  /* Sentinel */
};

static PyTypeObject CustomType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom2.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE
    .tp_new = Custom_new,
    .tp_init = (initproc) Custom_init,
    .tp_dealloc = (destructor) Custom_dealloc,
    .tp_members = Custom_members,
    .tp_methods = Custom_methods,
};

static PyModuleDef custommodule = {
```

```
    PyModuleDef_HEAD_INIT,
    .m_name = "custom2",
    .m_doc = "Example module that creates an extension t
    .m_size = -1,
};

PyMODINIT_FUNC
PyInit_custom2(void)
{
    PyObject *m;
    if (PyType_Ready(&CustomType) < 0)
        return NULL;

    m = PyModule_Create(&custommodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&CustomType);
    if (PyModule_AddObject(m, "Custom", (PyObject *) &Cu
        Py_DECREF(&CustomType);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

This version of the module has a number of changes.

We've added an extra include:

```
#include <structmember.h>
```

This include provides declarations that we use to handle attributes, as described a bit later.

The **`Custom`** type now has three data attributes in its C struct, *first*, *last*, and *number*. The *first* and *last* variables are Python strings containing first and last names. The *number* attribute is a C integer.

The object structure is updated accordingly:

```
typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;
```

Because we now have data to manage, we have to be more careful about object allocation and deallocation. At a minimum, we need a deallocation method:

```
static void
Custom_dealloc(CustomObject *self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject *) self);
}
```

which is assigned to the **`tp_dealloc`** member:

```
.tp_dealloc = (destructor) Custom_dealloc,
```

This method first clears the reference counts of the two Python attributes. **`Py_XDECREF()`** correctly handles the case where its argument is `NULL` (which might happen here if `tp_new` failed midway). It then calls the **`tp_free`** member of the object's type (computed by `Py_TYPE(self)`) to free the object's memory. Note that the object's type might not be **`CustomType`**, because the object may be an instance of a subclass.

Note

The explicit cast to `destructor` above is needed because we defined `Custom_dealloc` to take a `CustomObject *` argument, but the `tp_dealloc` function pointer expects to receive a `PyObject *` argument. Otherwise, the compiler will emit a warning. This is object-oriented polymorphism, in C!

We want to make sure that the first and last names are initialized to empty strings, so we provide a `tp_new` implementation:

```
static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
    }
    return (PyObject *) self;
}
```

and install it in the **`tp_new`** member:

```
.tp_new = Custom_new,
```

The `tp_new` handler is responsible for creating (as opposed to initializing) objects of the type. It is exposed in Python as the **`__new__()`** method. It is not required to define a `tp_new` member, and indeed many extension types will simply reuse **`PyType_GenericNew()`** as done in the first version of the `Custom` type above. In this case, we use the `tp_new` handler to initialize the `first` and `last` attributes to non-`NULL` default values.

`tp_new` is passed the type being instantiated (not necessarily `CustomType`, if a subclass is instantiated) and any arguments passed when the type was called, and is expected to return the

instance created. `tp_new` handlers always accept positional and keyword arguments, but they often ignore the arguments, leaving the argument handling to initializer (a.k.a. `tp_init` in C or `__init__` in Python) methods.

Note

`tp_new` shouldn't call `tp_init` explicitly, as the interpreter will do it itself.

The `tp_new` implementation calls the **`tp_alloc`** slot to allocate memory:

```
self = (CustomObject *) type->tp_alloc(type, 0);
```

Since memory allocation may fail, we must check the **`tp_alloc`** result against `NULL` before proceeding.

Note

We didn't fill the **`tp_alloc`** slot ourselves. Rather **`PyType_Ready()`** fills it for us by inheriting it from our base class, which is **`object`** by default. Most types use the default allocation strategy.

Note

If you are creating a co-operative **`tp_new`** (one that calls a base type's **`tp_new`** or **`__new__()`**), you must *not* try to determine what method to call using method resolution order at runtime. Always statically determine what type you are going to call, and call its **`tp_new`** directly, or via `type->tp_base->tp_new`. If you do not do this, Python subclasses of your type that also inherit from other Python-defined classes may not work correctly. (Specifically, you may not be able to create instances of such subclasses without getting a **`TypeError`**.)

We also define an initialization function which accepts arguments

to provide initial values for our instance:

```
static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL, *tmp;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|OOi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_XDECREF(tmp);
    }
    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_XDECREF(tmp);
    }
    return 0;
}
```

by filling the **`tp_init`** slot.

```
.tp_init = (initproc) Custom_init,
```

The **`tp_init`** slot is exposed in Python as the **`__init__()`** method. It is used to initialize an object after it's created. Initializers always accept positional and keyword arguments, and they should return either `0` on success or `-1` on error.

Unlike the `tp_new` handler, there is no guarantee that `tp_init` is called at all (for example, the **`pickle`** module by default doesn't call **`__init__()`** on unpickled instances). It can also be called

multiple times. Anyone can call the **`__init__()`** method on our objects. For this reason, we have to be extra careful when assigning the new attribute values. We might be tempted, for example to assign the `first` member like this:

```
if (first) {
    Py_XDECREF(self->first);
    Py_INCREF(first);
    self->first = first;
}
```

But this would be risky. Our type doesn't restrict the type of the `first` member, so it could be any kind of object. It could have a destructor that causes code to be executed that tries to access the `first` member; or that destructor could release the Global interpreter Lock and let arbitrary code run in other threads that accesses and modifies our object.

To be paranoid and protect ourselves against this possibility, we almost always reassign members before decrementing their reference counts. When don't we have to do this?

- when we absolutely know that the reference count is greater than 1;
- when we know that deallocation of the object 1 will neither release the GIL nor cause any calls back into our type's code;
- when decrementing a reference count in a **`tp_dealloc`** handler on a type which doesn't support cyclic garbage collection 2.

We want to expose our instance variables as attributes. There are a number of ways to do that. The simplest way is to define member definitions:

```
static PyMemberDef Custom_members[] = {
    {"first", T_OBJECT_EX, offsetof(CustomObject, first)
     "first name"},
    {"last", T_OBJECT_EX, offsetof(CustomObject, last),
     "last name"},
    {"number", T_INT, offsetof(CustomObject, number), 0,
```

```
     "custom number"},
    {NULL}  /* Sentinel */
};
```

and put the definitions in the **`tp_members`** slot:

```
.tp_members = Custom_members,
```

Each member definition has a member name, type, offset, access flags and documentation string. See the Generic Attribute Management section below for details.

A disadvantage of this approach is that it doesn't provide a way to restrict the types of objects that can be assigned to the Python attributes. We expect the first and last names to be strings, but any Python objects can be assigned. Further, the attributes can be deleted, setting the C pointers to `NULL`. Even though we can make sure the members are initialized to non-`NULL` values, the members can be set to `NULL` if the attributes are deleted.

We define a single method, **`Custom.name()`**, that outputs the objects name as the concatenation of the first and last names.

```
static PyObject *
Custom_name(CustomObject *self, PyObject *Py_UNUSED(igno
{
    if (self->first == NULL) {
        PyErr_SetString(PyExc_AttributeError, "first");
        return NULL;
    }
    if (self->last == NULL) {
        PyErr_SetString(PyExc_AttributeError, "last");
        return NULL;
    }
    return PyUnicode_FromFormat("%S %S", self->first, se
}
```

The method is implemented as a C function that takes a **`Custom`** (or **`Custom`** subclass) instance as the first argument. Methods always take an instance as the first argument. Methods often take

positional and keyword arguments as well, but in this case we don't take any and don't need to accept a positional argument tuple or keyword argument dictionary. This method is equivalent to the Python method:

```
def name(self):
    return "%s %s" % (self.first, self.last)
```

Note that we have to check for the possibility that our **`first`** and **`last`** members are `NULL`. This is because they can be deleted, in which case they are set to `NULL`. It would be better to prevent deletion of these attributes and to restrict the attribute values to be strings. We'll see how to do that in the next section.

Now that we've defined the method, we need to create an array of method definitions:

```
static PyMethodDef Custom_methods[] = {
    {"name", (PyCFunction) Custom_name, METH_NOARGS,
     "Return the name, combining the first and last name
    },
    {NULL}  /* Sentinel */
};
```

(note that we used the **`METH_NOARGS`** flag to indicate that the method is expecting no arguments other than *self*)

and assign it to the **`tp_methods`** slot:

```
.tp_methods = Custom_methods,
```

Finally, we'll make our type usable as a base class for subclassing. We've written our methods carefully so far so that they don't make any assumptions about the type of the object being created or used, so all we need to do is to add the **`Py_TPFLAGS_BASETYPE`** to our class flag definition:

```
.tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE,
```

We rename **`PyInit_custom()`** to **`PyInit_custom2()`**, update the module name in the **`PyModuleDef`** struct, and update the full

class name in the **`PyTypeObject`** struct.

Finally, we update our `setup.py` file to build the new module:

```
from distutils.core import setup, Extension
setup(name="custom", version="1.0",
      ext_modules=[
         Extension("custom", ["custom.c"]),
         Extension("custom2", ["custom2.c"]),
         ])
```

2.3. Providing finer control over data attributes

In this section, we'll provide finer control over how the **`first`** and **`last`** attributes are set in the **`Custom`** example. In the previous version of our module, the instance variables **`first`** and **`last`** could be set to non-string values or even deleted. We want to make sure that these attributes always contain strings.

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;

static void
Custom_dealloc(CustomObject *self)
{
    Py_XDECREF(self->first);
    Py_XDECREF(self->last);
    Py_TYPE(self)->tp_free((PyObject *) self);
}
```

```
static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
    }
    return (PyObject *) self;
}

static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL, *tmp;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|UUi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
```

```
    }
    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }
    return 0;
}

static PyMemberDef Custom_members[] = {
    {"number", T_INT, offsetof(CustomObject, number), 0,
     "custom number"},
    {NULL}  /* Sentinel */
};

static PyObject *
Custom_getfirst(CustomObject *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Custom_setfirst(CustomObject *self, PyObject *value, voi
{
    PyObject *tmp;
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete
        return -1;
    }
    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
                        "The first attribute value must
        return -1;
    }
    tmp = self->first;
    Py_INCREF(value);
```

```
    self->first = value;
    Py_DECREF(tmp);
    return 0;
}

static PyObject *
Custom_getlast(CustomObject *self, void *closure)
{
    Py_INCREF(self->last);
    return self->last;
}

static int
Custom_setlast(CustomObject *self, PyObject *value, voic
{
    PyObject *tmp;
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete
        return -1;
    }
    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
                        "The last attribute value must b
        return -1;
    }
    tmp = self->last;
    Py_INCREF(value);
    self->last = value;
    Py_DECREF(tmp);
    return 0;
}

static PyGetSetDef Custom_getsetters[] = {
    {"first", (getter) Custom_getfirst, (setter) Custom_
     "first name", NULL},
    {"last", (getter) Custom_getlast, (setter) Custom_se
     "last name", NULL},
    {NULL}  /* Sentinel */
```

```
};

static PyObject *
Custom_name(CustomObject *self, PyObject *Py_UNUSED(ignc
{
    return PyUnicode_FromFormat("%S %S", self->first, se
}

static PyMethodDef Custom_methods[] = {
    {"name", (PyCFunction) Custom_name, METH_NOARGS,
     "Return the name, combining the first and last name
    },
    {NULL}  /* Sentinel */
};

static PyTypeObject CustomType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom3.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE
    .tp_new = Custom_new,
    .tp_init = (initproc) Custom_init,
    .tp_dealloc = (destructor) Custom_dealloc,
    .tp_members = Custom_members,
    .tp_methods = Custom_methods,
    .tp_getset = Custom_getsetters,
};

static PyModuleDef custommodule = {
    PyModuleDef_HEAD_INIT,
    .m_name = "custom3",
    .m_doc = "Example module that creates an extension t
    .m_size = -1,
};

PyMODINIT_FUNC
```

```
PyInit_custom3(void)
{
    PyObject *m;
    if (PyType_Ready(&CustomType) < 0)
        return NULL;

    m = PyModule_Create(&custommodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&CustomType);
    if (PyModule_AddObject(m, "Custom", (PyObject *) &Cu
        Py_DECREF(&CustomType);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

To provide greater control, over the **`first`** and **`last`** attributes, we'll use custom getter and setter functions. Here are the functions for getting and setting the **`first`** attribute:

```
static PyObject *
Custom_getfirst(CustomObject *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Custom_setfirst(CustomObject *self, PyObject *value, voi
{
    PyObject *tmp;
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete
        return -1;
    }
```

```
    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
                        "The first attribute value must
        return -1;
    }
    tmp = self->first;
    Py_INCREF(value);
    self->first = value;
    Py_DECREF(tmp);
    return 0;
}
```

The getter function is passed a **`Custom`** object and a "closure", which is a void pointer. In this case, the closure is ignored. (The closure supports an advanced usage in which definition data is passed to the getter and setter. This could, for example, be used to allow a single set of getter and setter functions that decide the attribute to get or set based on data in the closure.)

The setter function is passed the **`Custom`** object, the new value, and the closure. The new value may be `NULL`, in which case the attribute is being deleted. In our setter, we raise an error if the attribute is deleted or if its new value is not a string.

We create an array of **`PyGetSetDef`** structures:

```
static PyGetSetDef Custom_getsetters[] = {
    {"first", (getter) Custom_getfirst, (setter) Custom_
     "first name", NULL},
    {"last", (getter) Custom_getlast, (setter) Custom_se
     "last name", NULL},
    {NULL}  /* Sentinel */
};
```

and register it in the **`tp_getset`** slot:

```
.tp_getset = Custom_getsetters,
```

The last item in a **`PyGetSetDef`** structure is the "closure" mentioned above. In this case, we aren't using a closure, so we just

pass `NULL`.

We also remove the member definitions for these attributes:

```
static PyMemberDef Custom_members[] = {
    {"number", T_INT, offsetof(CustomObject, number), 0,
     "custom number"},
    {NULL}  /* Sentinel */
};
```

We also need to update the **`tp_init`** handler to only allow strings 3 to be passed:

```
static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL, *tmp;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|UUi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }
    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }
    return 0;
}
```

With these changes, we can assure that the `first` and `last`

members are never `NULL` so we can remove checks for `NULL` values in almost all cases. This means that most of the **`Py_XDECREF()`** calls can be converted to **`Py_DECREF()`** calls. The only place we can't change these calls is in the `tp_dealloc` implementation, where there is the possibility that the initialization of these members failed in `tp_new`.

We also rename the module initialization function and module name in the initialization function, as we did before, and we add an extra definition to the `setup.py` file.

2.4. Supporting cyclic garbage collection

Python has a cyclic garbage collector (GC) that can identify unneeded objects even when their reference counts are not zero. This can happen when objects are involved in cycles. For example, consider:

```
>>> l = []
>>> l.append(l)
>>> del l
```

In this example, we create a list that contains itself. When we delete it, it still has a reference from itself. Its reference count doesn't drop to zero. Fortunately, Python's cyclic garbage collector will eventually figure out that the list is garbage and free it.

In the second version of the **`Custom`** example, we allowed any kind of object to be stored in the **`first`** or **`last`** attributes 4. Besides, in the second and third versions, we allowed subclassing **`Custom`**, and subclasses may add arbitrary attributes. For any of those two reasons, **`Custom`** objects can participate in cycles:

```
>>> import custom3
>>> class Derived(custom3.Custom): pass
...
>>> n = Derived()
>>> n.some_attribute = n
```

To allow a **`Custom`** instance participating in a reference cycle to be

properly detected and collected by the cyclic GC, our **`Custom`** type needs to fill two additional slots and to enable a flag that enables these slots:

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>
#include "structmember.h"

typedef struct {
    PyObject_HEAD
    PyObject *first; /* first name */
    PyObject *last;  /* last name */
    int number;
} CustomObject;

static int
Custom_traverse(CustomObject *self, visitproc visit, voi
{
    Py_VISIT(self->first);
    Py_VISIT(self->last);
    return 0;
}

static int
Custom_clear(CustomObject *self)
{
    Py_CLEAR(self->first);
    Py_CLEAR(self->last);
    return 0;
}

static void
Custom_dealloc(CustomObject *self)
{
    PyObject_GC_UnTrack(self);
    Custom_clear(self);
    Py_TYPE(self)->tp_free((PyObject *) self);
}
```

```
static PyObject *
Custom_new(PyTypeObject *type, PyObject *args, PyObject
{
    CustomObject *self;
    self = (CustomObject *) type->tp_alloc(type, 0);
    if (self != NULL) {
        self->first = PyUnicode_FromString("");
        if (self->first == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->last = PyUnicode_FromString("");
        if (self->last == NULL) {
            Py_DECREF(self);
            return NULL;
        }
        self->number = 0;
    }
    return (PyObject *) self;
}

static int
Custom_init(CustomObject *self, PyObject *args, PyObject
{
    static char *kwlist[] = {"first", "last", "number",
    PyObject *first = NULL, *last = NULL, *tmp;

    if (!PyArg_ParseTupleAndKeywords(args, kwds, "|UUi",
                                     &first, &last,
                                     &self->number))
        return -1;

    if (first) {
        tmp = self->first;
        Py_INCREF(first);
        self->first = first;
        Py_DECREF(tmp);
    }
```

```
    if (last) {
        tmp = self->last;
        Py_INCREF(last);
        self->last = last;
        Py_DECREF(tmp);
    }
    return 0;
}

static PyMemberDef Custom_members[] = {
    {"number", T_INT, offsetof(CustomObject, number), 0,
     "custom number"},
    {NULL}  /* Sentinel */
};

static PyObject *
Custom_getfirst(CustomObject *self, void *closure)
{
    Py_INCREF(self->first);
    return self->first;
}

static int
Custom_setfirst(CustomObject *self, PyObject *value, voi
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete
        return -1;
    }
    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
                        "The first attribute value must
        return -1;
    }
    Py_INCREF(value);
    Py_CLEAR(self->first);
    self->first = value;
    return 0;
```

```
}

static PyObject *
Custom_getlast(CustomObject *self, void *closure)
{
    Py_INCREF(self->last);
    return self->last;
}

static int
Custom_setlast(CustomObject *self, PyObject *value, voic
{
    if (value == NULL) {
        PyErr_SetString(PyExc_TypeError, "Cannot delete
        return -1;
    }
    if (!PyUnicode_Check(value)) {
        PyErr_SetString(PyExc_TypeError,
                        "The last attribute value must b
        return -1;
    }
    Py_INCREF(value);
    Py_CLEAR(self->last);
    self->last = value;
    return 0;
}

static PyGetSetDef Custom_getsetters[] = {
    {"first", (getter) Custom_getfirst, (setter) Custom_
     "first name", NULL},
    {"last", (getter) Custom_getlast, (setter) Custom_se
     "last name", NULL},
    {NULL}  /* Sentinel */
};

static PyObject *
Custom_name(CustomObject *self, PyObject *Py_UNUSED(ignc
{
```

```
    return PyUnicode_FromFormat("%S %S", self->first, se
}

static PyMethodDef Custom_methods[] = {
    {"name", (PyCFunction) Custom_name, METH_NOARGS,
     "Return the name, combining the first and last name
    },
    {NULL}  /* Sentinel */
};

static PyTypeObject CustomType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "custom4.Custom",
    .tp_doc = PyDoc_STR("Custom objects"),
    .tp_basicsize = sizeof(CustomObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE
    .tp_new = Custom_new,
    .tp_init = (initproc) Custom_init,
    .tp_dealloc = (destructor) Custom_dealloc,
    .tp_traverse = (traverseproc) Custom_traverse,
    .tp_clear = (inquiry) Custom_clear,
    .tp_members = Custom_members,
    .tp_methods = Custom_methods,
    .tp_getset = Custom_getsetters,
};

static PyModuleDef custommodule = {
    PyModuleDef_HEAD_INIT,
    .m_name = "custom4",
    .m_doc = "Example module that creates an extension t
    .m_size = -1,
};

PyMODINIT_FUNC
PyInit_custom4(void)
{
    PyObject *m;
```

```
    if (PyType_Ready(&CustomType) < 0)
        return NULL;

    m = PyModule_Create(&custommodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&CustomType);
    if (PyModule_AddObject(m, "Custom", (PyObject *) &Cu
        Py_DECREF(&CustomType);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

First, the traversal method lets the cyclic GC know about subobjects that could participate in cycles:

```
static int
Custom_traverse(CustomObject *self, visitproc visit, voi
{
    int vret;
    if (self->first) {
        vret = visit(self->first, arg);
        if (vret != 0)
            return vret;
    }
    if (self->last) {
        vret = visit(self->last, arg);
        if (vret != 0)
            return vret;
    }
    return 0;
}
```

For each subobject that can participate in cycles, we need to call the **`visit()`** function, which is passed to the traversal method. The

`visit()` function takes as arguments the subobject and the extra argument *arg* passed to the traversal method. It returns an integer value that must be returned if it is non-zero.

Python provides a **`Py_VISIT()`** macro that automates calling visit functions. With **`Py_VISIT()`**, we can minimize the amount of boilerplate in `Custom_traverse`:

```
static int
Custom_traverse(CustomObject *self, visitproc visit, voi
{
    Py_VISIT(self->first);
    Py_VISIT(self->last);
    return 0;
}
```

Note

The **`tp_traverse`** implementation must name its arguments exactly *visit* and *arg* in order to use **`Py_VISIT()`**.

Second, we need to provide a method for clearing any subobjects that can participate in cycles:

```
static int
Custom_clear(CustomObject *self)
{
    Py_CLEAR(self->first);
    Py_CLEAR(self->last);
    return 0;
}
```

Notice the use of the **`Py_CLEAR()`** macro. It is the recommended and safe way to clear data attributes of arbitrary types while decrementing their reference counts. If you were to call **`Py_XDECREF()`** instead on the attribute before setting it to `NULL`, there is a possibility that the attribute's destructor would call back into code that reads the attribute again (*especially* if there is a reference cycle).

Note

You could emulate `Py_CLEAR()` by writing:

```
PyObject *tmp;
tmp = self->first;
self->first = NULL;
Py_XDECREF(tmp);
```

Nevertheless, it is much easier and less error-prone to always use `Py_CLEAR()` when deleting an attribute. Don't try to micro-optimize at the expense of robustness!

The deallocator `Custom_dealloc` may call arbitrary code when clearing attributes. It means the circular GC can be triggered inside the function. Since the GC assumes reference count is not zero, we need to untrack the object from the GC by calling `PyObject_GC_UnTrack()` before clearing members. Here is our reimplemented deallocator using `PyObject_GC_UnTrack()` and `Custom_clear`:

```
static void
Custom_dealloc(CustomObject *self)
{
    PyObject_GC_UnTrack(self);
    Custom_clear(self);
    Py_TYPE(self)->tp_free((PyObject *) self);
}
```

Finally, we add the `Py_TPFLAGS_HAVE_GC` flag to the class flags:

```
.tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE | P
```

That's pretty much it. If we had written custom `tp_alloc` or `tp_free` handlers, we'd need to modify them for cyclic garbage collection. Most extensions will use the versions automatically provided.

2.5. Subclassing other types

It is possible to create new extension types that are derived from existing types. It is easiest to inherit from the built in types, since an extension can easily use the **`PyTypeObject`** it needs. It can be difficult to share these **`PyTypeObject`** structures between extension modules.

In this example we will create a **`SubList`** type that inherits from the built-in **`list`** type. The new type will be completely compatible with regular lists, but will have an additional **`increment()`** method that increases an internal counter:

```
>>> import sublist
>>> s = sublist.SubList(range(3))
>>> s.extend(s)
>>> print(len(s))
6
>>> print(s.increment())
1
>>> print(s.increment())
2
```

```
#define PY_SSIZE_T_CLEAN
#include <Python.h>

typedef struct {
    PyListObject list;
    int state;
} SubListObject;

static PyObject *
SubList_increment(SubListObject *self, PyObject *unused)
{
    self->state++;
    return PyLong_FromLong(self->state);
}

static PyMethodDef SubList_methods[] = {
    {"increment", (PyCFunction) SubList_increment, METH_
     PyDoc_STR("increment state counter")},
```

```
    {NULL},
};

static int
SubList_init(SubListObject *self, PyObject *args, PyObje
{
    if (PyList_Type.tp_init((PyObject *) self, args, kwo
        return -1;
    self->state = 0;
    return 0;
}

static PyTypeObject SubListType = {
    PyVarObject_HEAD_INIT(NULL, 0)
    .tp_name = "sublist.SubList",
    .tp_doc = PyDoc_STR("SubList objects"),
    .tp_basicsize = sizeof(SubListObject),
    .tp_itemsize = 0,
    .tp_flags = Py_TPFLAGS_DEFAULT | Py_TPFLAGS_BASETYPE
    .tp_init = (initproc) SubList_init,
    .tp_methods = SubList_methods,
};

static PyModuleDef sublistmodule = {
    PyModuleDef_HEAD_INIT,
    .m_name = "sublist",
    .m_doc = "Example module that creates an extension t
    .m_size = -1,
};

PyMODINIT_FUNC
PyInit_sublist(void)
{
    PyObject *m;
    SubListType.tp_base = &PyList_Type;
    if (PyType_Ready(&SubListType) < 0)
        return NULL;
```

```
    m = PyModule_Create(&sublistmodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&SubListType);
    if (PyModule_AddObject(m, "SubList", (PyObject *) &S
        Py_DECREF(&SubListType);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

As you can see, the source code closely resembles the **`Custom`** examples in previous sections. We will break down the main differences between them.

```
typedef struct {
    PyListObject list;
    int state;
} SubListObject;
```

The primary difference for derived type objects is that the base type's object structure must be the first value. The base type will already include the **`PyObject_HEAD()`** at the beginning of its structure.

When a Python object is a **`SubList`** instance, its `PyObject *` pointer can be safely cast to both `PyListObject *` and `SubListObject *`:

```
static int
SubList_init(SubListObject *self, PyObject *args, PyObje
{
    if (PyList_Type.tp_init((PyObject *) self, args, kwo
        return -1;
    self->state = 0;
    return 0;
}
```

We see above how to call through to the **__init__** method of the base type.

This pattern is important when writing a type with custom **tp_new** and **tp_dealloc** members. The **tp_new** handler should not actually create the memory for the object with its **tp_alloc**, but let the base class handle it by calling its own **tp_new**.

The **PyTypeObject** struct supports a **tp_base** specifying the type's concrete base class. Due to cross-platform compiler issues, you can't fill that field directly with a reference to **PyList_Type**; it should be done later in the module initialization function:

```
PyMODINIT_FUNC
PyInit_sublist(void)
{
    PyObject* m;
    SubListType.tp_base = &PyList_Type;
    if (PyType_Ready(&SubListType) < 0)
        return NULL;

    m = PyModule_Create(&sublistmodule);
    if (m == NULL)
        return NULL;

    Py_INCREF(&SubListType);
    if (PyModule_AddObject(m, "SubList", (PyObject *) &S
        Py_DECREF(&SubListType);
        Py_DECREF(m);
        return NULL;
    }

    return m;
}
```

Before calling **PyType_Ready()**, the type structure must have the **tp_base** slot filled in. When we are deriving an existing type, it is not necessary to fill out the **tp_alloc** slot with **PyType_GenericNew()** – the allocation function from the base type will be inherited.

After that, calling `PyType_Ready()` and adding the type object to the module is the same as with the basic `Custom` examples.

Footnotes

1

This is true when we know that the object is a basic type, like a string or a float.

2

We relied on this in the `tp_dealloc` handler in this example, because our type doesn't support garbage collection.

3

We now know that the first and last members are strings, so perhaps we could be less careful about decrementing their reference counts, however, we accept instances of string subclasses. Even though deallocating normal strings won't call back into our objects, we can't guarantee that deallocating an instance of a string subclass won't call back into our objects.

4

Also, even with our attributes restricted to strings instances, the user could pass arbitrary `str` subclasses and therefore still create reference cycles.

3. Defining Extension Types: Assorted Topics

This section aims to give a quick fly-by on the various type methods you can implement and what they do.

Here is the definition of **`PyTypeObject`**, with some fields only used in debug builds omitted:

```
typedef struct _typeobject {
    PyObject_VAR_HEAD
    const char *tp_name; /* For printing, in format "<mo
    Py_ssize_t tp_basicsize, tp_itemsize; /* For allocat

    /* Methods to implement standard operations */

    destructor tp_dealloc;
    Py_ssize_t tp_vectorcall_offset;
    getattrfunc tp_getattr;
    setattrfunc tp_setattr;
    PyAsyncMethods *tp_as_async; /* formerly known as tp
                                    or tp_reserved (Pyth
    reprfunc tp_repr;

    /* Method suites for standard classes */

    PyNumberMethods *tp_as_number;
    PySequenceMethods *tp_as_sequence;
    PyMappingMethods *tp_as_mapping;

    /* More standard operations (here for binary compati

    hashfunc tp_hash;
    ternaryfunc tp_call;
```

```
reprfunc tp_str;
getattrofunc tp_getattro;
setattrofunc tp_setattro;

/* Functions to access object as input/output buffer
PyBufferProcs *tp_as_buffer;

/* Flags to define presence of optional/expanded fea
unsigned long tp_flags;

const char *tp_doc; /* Documentation string */

/* Assigned meaning in release 2.0 */
/* call function for all accessible objects */
traverseproc tp_traverse;

/* delete references to contained objects */
inquiry tp_clear;

/* Assigned meaning in release 2.1 */
/* rich comparisons */
richcmpfunc tp_richcompare;

/* weak reference enabler */
Py_ssize_t tp_weaklistoffset;

/* Iterators */
getiterfunc tp_iter;
iternextfunc tp_iternext;

/* Attribute descriptor and subclassing stuff */
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
// Strong reference on a heap type, borrowed referen
struct _typeobject *tp_base;
PyObject *tp_dict;
descrgetfunc tp_descr_get;
```

```
    descrsetfunc tp_descr_set;
    Py_ssize_t tp_dictoffset;
    initproc tp_init;
    allocfunc tp_alloc;
    newfunc tp_new;
    freefunc tp_free; /* Low-level free-memory routine *
    inquiry tp_is_gc; /* For PyObject_IS_GC */
    PyObject *tp_bases;
    PyObject *tp_mro; /* method resolution order */
    PyObject *tp_cache;
    PyObject *tp_subclasses;
    PyObject *tp_weaklist;
    destructor tp_del;

    /* Type attribute cache version tag. Added in versio
    unsigned int tp_version_tag;

    destructor tp_finalize;
    vectorcallfunc tp_vectorcall;
} PyTypeObject;
```

Now that's a *lot* of methods. Don't worry too much though – if you have a type you want to define, the chances are very good that you will only implement a handful of these.

As you probably expect by now, we're going to go over this and give more information about the various handlers. We won't go in the order they are defined in the structure, because there is a lot of historical baggage that impacts the ordering of the fields. It's often easiest to find an example that includes the fields you need and then change the values to suit your new type.

```
const char *tp_name; /* For printing */
```

The name of the type – as mentioned in the previous chapter, this will appear in various places, almost entirely for diagnostic purposes. Try to choose something that will be helpful in such a situation!

```
Py_ssize_t tp_basicsize, tp_itemsize; /* For allocation
```

These fields tell the runtime how much memory to allocate when new objects of this type are created. Python has some built-in support for variable length structures (think: strings, tuples) which is where the **tp_itemsize** field comes in. This will be dealt with later.

```
const char *tp_doc;
```

Here you can put a string (or its address) that you want returned when the Python script references `obj.__doc__` to retrieve the doc string.

Now we come to the basic type methods – the ones most extension types will implement.

3.1. Finalization and De-allocation

```
destructor tp_dealloc;
```

This function is called when the reference count of the instance of your type is reduced to zero and the Python interpreter wants to reclaim it. If your type has memory to free or other clean-up to perform, you can put it here. The object itself needs to be freed here as well. Here is an example of this function:

```
static void
newdatatype_dealloc(newdatatypeobject *obj)
{
    free(obj->obj_UnderlyingDatatypePtr);
    Py_TYPE(obj)->tp_free((PyObject *)obj);
}
```

If your type supports garbage collection, the destructor should call **PyObject_GC_UnTrack()** before clearing any member fields:

```
static void
newdatatype_dealloc(newdatatypeobject *obj)
{
    PyObject_GC_UnTrack(obj);
    Py_CLEAR(obj->other_obj);
```

```
    ...
    Py_TYPE(obj)->tp_free((PyObject *)obj);
}
```

One important requirement of the deallocator function is that it leaves any pending exceptions alone. This is important since deallocators are frequently called as the interpreter unwinds the Python stack; when the stack is unwound due to an exception (rather than normal returns), nothing is done to protect the deallocators from seeing that an exception has already been set. Any actions which a deallocator performs which may cause additional Python code to be executed may detect that an exception has been set. This can lead to misleading errors from the interpreter. The proper way to protect against this is to save a pending exception before performing the unsafe action, and restoring it when done. This can be done using the **PyErr_Fetch()** and **PyErr_Restore()** functions:

```
static void
my_dealloc(PyObject *obj)
{
    MyObject *self = (MyObject *) obj;
    PyObject *cbresult;

    if (self->my_callback != NULL) {
        PyObject *err_type, *err_value, *err_traceback;

        /* This saves the current exception state */
        PyErr_Fetch(&err_type, &err_value, &err_traceba

        cbresult = PyObject_CallNoArgs(self->my_callback
        if (cbresult == NULL)
            PyErr_WriteUnraisable(self->my_callback);
        else
            Py_DECREF(cbresult);

        /* This restores the saved exception state */
        PyErr_Restore(err_type, err_value, err_traceback
```

```
        Py_DECREF(self->my_callback);
    }
    Py_TYPE(obj)->tp_free((PyObject*)self);
}
```

Note

There are limitations to what you can safely do in a deallocator function. First, if your type supports garbage collection (using **tp_traverse** and/or **tp_clear**), some of the object's members can have been cleared or finalized by the time **tp_dealloc** is called. Second, in **tp_dealloc**, your object is in an unstable state: its reference count is equal to zero. Any call to a non-trivial object or API (as in the example above) might end up calling **tp_dealloc** again, causing a double free and a crash.

Starting with Python 3.4, it is recommended not to put any complex finalization code in **tp_dealloc**, and instead use the new **tp_finalize** type method.

See also

PEP 442 [https://peps.python.org/pep-0442/] explains the new finalization scheme.

3.2. Object Presentation

In Python, there are two ways to generate a textual representation of an object: the **repr()** function, and the **str()** function. (The **print()** function just calls **str()**.) These handlers are both optional.

```
reprfunc tp_repr;
reprfunc tp_str;
```

The **tp_repr** handler should return a string object containing a

representation of the instance for which it is called. Here is a simple example:

```
static PyObject *
newdatatype_repr(newdatatypeobject * obj)
{
    return PyUnicode_FromFormat("Repr-ified_newdatatype{
                                obj->obj_UnderlyingDatat
}
```

If no **tp_repr** handler is specified, the interpreter will supply a representation that uses the type's **tp_name** and a uniquely identifying value for the object.

The **tp_str** handler is to **str()** what the **tp_repr** handler described above is to **repr()**; that is, it is called when Python code calls **str()** on an instance of your object. Its implementation is very similar to the **tp_repr** function, but the resulting string is intended for human consumption. If **tp_str** is not specified, the **tp_repr** handler is used instead.

Here is a simple example:

```
static PyObject *
newdatatype_str(newdatatypeobject * obj)
{
    return PyUnicode_FromFormat("Stringified_newdatatype
                                obj->obj_UnderlyingDatat
}
```

3.3. Attribute Management

For every object which can support attributes, the corresponding type must provide the functions that control how the attributes are resolved. There needs to be a function which can retrieve attributes (if any are defined), and another to set attributes (if setting attributes is allowed). Removing an attribute is a special case, for which the new value passed to the handler is `NULL`.

Python supports two pairs of attribute handlers; a type that

supports attributes only needs to implement the functions for one pair. The difference is that one pair takes the name of the attribute as a char*, while the other accepts a PyObject*. Each type can use whichever pair makes more sense for the implementation's convenience.

```
getattrfunc  tp_getattr;        /* char * version */
setattrfunc  tp_setattr;
/* ... */
getattrofunc tp_getattro;       /* PyObject * version */
setattrofunc tp_setattro;
```

If accessing attributes of an object is always a simple operation (this will be explained shortly), there are generic implementations which can be used to provide the PyObject* version of the attribute management functions. The actual need for type-specific attribute handlers almost completely disappeared starting with Python 2.2, though there are many examples which have not been updated to use some of the new generic mechanism that is available.

3.3.1. Generic Attribute Management

Most extension types only use *simple* attributes. So, what makes the attributes simple? There are only a couple of conditions that must be met:

1. The name of the attributes must be known when **`PyType_Ready()`** is called.
2. No special processing is needed to record that an attribute was looked up or set, nor do actions need to be taken based on the value.

Note that this list does not place any restrictions on the values of the attributes, when the values are computed, or how relevant data is stored.

When **`PyType_Ready()`** is called, it uses three tables referenced by the type object to create descriptors which are placed in the dictionary of the type object. Each descriptor controls access to one attribute of the instance object. Each of the tables is optional; if all

three are `NULL`, instances of the type will only have attributes that are inherited from their base type, and should leave the **`tp_getattro`** and **`tp_setattro`** fields `NULL` as well, allowing the base type to handle attributes.

The tables are declared as three fields of the type object:

```
struct PyMethodDef *tp_methods;
struct PyMemberDef *tp_members;
struct PyGetSetDef *tp_getset;
```

If **`tp_methods`** is not `NULL`, it must refer to an array of **`PyMethodDef`** structures. Each entry in the table is an instance of this structure:

```
typedef struct PyMethodDef {
    const char  *ml_name;       /* method name */
    PyCFunction  ml_meth;       /* implementation functi
    int          ml_flags;      /* flags */
    const char  *ml_doc;        /* docstring */
} PyMethodDef;
```
